Sovereign Cloud Operations: IBM Sales Play Guide

Positioning, Qualification, and Execution for IBM Sellers

Derived from Sovereign Cloud Operations *by Alan Hamilton*

Part I — Concept and Market Context

1. The Sovereign Cloud Operations Opportunity

1.1 What Is Sovereign Cloud Operations?

Sovereign cloud operations is the discipline of maintaining continuous, auditable, policy-governed control over the entire operational lifecycle of a multi-cloud estate—spanning public clouds (AWS, Azure, GCP), on-premises data centres, and edge locations—whilst respecting jurisdictional boundaries, regulatory obligations, and organisational sovereignty requirements.

It is not about replacing hyperscaler infrastructure. It is about providing the cross-cloud control and intelligence layer that no single hyperscaler can deliver, because no hyperscaler has an incentive to make their competitors' platforms equally visible and manageable.

The discipline rests on a distinction that resonates immediately with C-suite audiences: the difference between *infrastructure sovereignty* (knowing where data resides) and *operational sovereignty* (knowing who can act on which systems, from which jurisdictions, under which policies, and how those actions are governed, audited, and explained). Infrastructure sovereignty is necessary but insufficient. Operational sovereignty is what regulators, boards, and clients now demand.

Sovereign cloud operations addresses three structural gaps that every enterprise with multi-cloud ambitions eventually encounters:

1. **The visibility gap.** Hyperscaler-native monitoring tools see their own platform deeply but are architecturally blind to what happens on competitors' infrastructure. An organisation running workloads across AWS, Azure, and on-premises OpenShift has three separate views of operational health, none of which shows the cross-cloud dependency chain that determines business-service availability. When an incident occurs, teams waste critical minutes navigating between consoles, correlating timestamps manually, and arguing about which layer owns the fault. IBM's observability and AIOps stack—Instana, Concert, Turbonomic—provides the single pane of glass that spans all three.

2. **The governance gap.** Compliance teams can often demonstrate where data resides (infrastructure sovereignty), but they cannot demonstrate who accessed which operational controls, from which jurisdiction, under which policy, at what time, and whether that action was auditable and explainable (operational sovereignty). As regulations such as DORA, NIS2, and the EU AI Act mature, the governance gap becomes an audit finding, a regulatory fine, or a board-level risk.

3. **The intelligence gap.** The volume of operational telemetry in a multi-cloud estate exceeds human capacity to process. Alert storms during major incidents can generate hundreds of notifications across disconnected tools. Without AI-driven correlation, triage, and recommended remediation, operations teams remain in reactive mode—fighting fires rather than preventing them.

   WIIFM: Every enterprise you call on that runs workloads on more than one cloud has these three gaps. The conversation opener is not "let me sell you IBM software"—it is "how do you maintain a single, governed view of operations across your entire estate today?" The answer, overwhelmingly, is that they do not.

1.2 Why Now?

Four converging forces make this the right moment for sovereign cloud operations:

Regulatory pressure is accelerating. DORA (Digital Operational Resilience Act) applies to EU financial entities from January 2025, requiring demonstrable ICT risk management, incident reporting within four hours, and regular digital operational resilience testing—including of third-party cloud providers. NIS2 broadens cyber-security obligations to essential and important entities across energy, transport, health, and digital infrastructure. The EU AI Act imposes transparency and governance requirements on AI systems used in critical infrastructure. These are not future possibilities; they are current compliance obligations with material penalties. DORA fines can reach 1% of average daily worldwide turnover; NIS2 penalties can reach EUR 10 million or 2% of global turnover. Organisations that cannot demonstrate operational governance across their multi-cloud estate face direct financial exposure.

Multi-cloud is no longer optional. Analyst surveys consistently show that 80–90% of large enterprises use two or more public cloud providers, not by strategic design but by organic growth—acquisitions, team preferences, best-of-breed service selection, and the pragmatic reality that no single provider excels at everything. Each additional cloud multiplies the operational surface area: more APIs to monitor, more identity systems to integrate, more compliance boundaries to enforce, more runbooks to maintain. The operational cost of multi-cloud grows faster than the infrastructure cost.

The talent gap is structural. Operations teams are under-staffed, over-worked, and losing experienced engineers to burnout and attrition. The work is disproportionately reactive: responding to alerts, manually correlating signals across tools, executing repetitive runbooks, and producing compliance evidence by hand. These are precisely the tasks that AI-driven operations can automate or augment, freeing human

engineers for the architectural and judgement work that only humans can do. Organisations that fail to automate operational toil will continue to lose talent to organisations that do.

AI has reached operational maturity. Large language models and agentic AI systems have matured to the point where they can reliably perform operational tasks—correlating alerts, drafting remediation plans, executing multi-step workflows with human approval gates—with the governance controls necessary for regulated environments. This is not speculative; IBM Concert and watsonx Orchestrate are production systems deployed in financial services, telecommunications, and government. The question is no longer whether AI can assist operations but whether an organisation can afford to operate without it.

> **WIIFM:** The combination of regulatory deadlines (DORA, NIS2), multi-cloud complexity, talent scarcity, and AI maturity creates a buying window that will not stay open indefinitely. Organisations that delay will face higher compliance costs, higher operational risk, and a widening gap between their operational capabilities and their regulatory obligations. Position yourself as the seller who connects these dots before the competition does.

1.3 The Economic Argument

The traditional cost model for cloud operations focused on infrastructure unit prices: compute, storage, network, reserved versus on-demand pricing. That model is obsolete. In a sovereign, multi-cloud estate, the dominant costs are operational, not infrastructural:

Incident cost. The fully loaded cost of a major incident includes not just the engineering hours spent in the war room but the revenue lost during downtime, the reputational damage, the regulatory reporting effort, and the post-incident remediation. Industry data consistently shows that the mean cost of a critical production incident in a large financial institution is between USD 100,000 and USD 500,000. For tier-one outages, figures exceeding USD 1 million are not uncommon. Reducing mean time to detect (MTTD) and mean time to resolve (MTTR) by even 30% translates directly to avoided cost that dwarfs the investment in AIOps tooling.

Toil cost. Operations teams spend between 40% and 60% of their time on toil—repetitive, automatable tasks that produce no lasting value. Certificate renewals, log reviews, capacity adjustments, compliance evidence gathering, alert triage—all performed manually, repeatedly, across every cloud in the estate. At a fully loaded cost of USD 150,000–200,000 per operations engineer per year, toil consumes millions of dollars annually in a mid-size enterprise. Automation does not eliminate operations jobs; it redirects engineering capacity from toil to value-creating work: architecture, reliability engineering, security improvement.

Regulatory fine risk. Under DORA, NIS2, and comparable frameworks, the financial exposure for non-compliance is quantifiable and material. A DORA fine of 1% of average daily worldwide turnover for a bank with EUR 10 billion in annual revenue is EUR 274,000 per day. NIS2 penalties can reach EUR 10 million. These are not theoretical maxima; they are the numbers that risk committees and boards use in their risk registers. The cost of implementing sovereign operations governance is a fraction of the potential fine exposure.

Talent attrition cost. Replacing an experienced site reliability engineer costs between 1.5 and 2 times their annual compensation when recruiting, onboarding, and lost productivity are factored in. If burnout-driven attrition costs an organisation three senior engineers per year, the replacement cost alone is USD 600,000–900,000, not counting the institutional knowledge that walks out the door and the impact on the remaining team.

Opportunity cost. Every hour an engineer spends on manual toil is an hour not spent on platform improvement, security hardening, or new capability delivery. This opportunity cost is invisible in most operational budgets but is often the largest single cost category. Organisations that automate operational toil can redirect 30–40% of engineering capacity to proactive work within the first year.

The business case for sovereign cloud operations is not "buy more software." It is "redirect operational spend from waste to value, reduce regulatory exposure, and retain your best engineers." The IBM portfolio is the mechanism; the economic outcome is the message.

> **WIIFM:** When you can quantify the customer's current cost of incidents, toil, regulatory risk, and attrition—and show that the IBM investment pays for itself within 12–18 months—you move the conversation from IT procurement to business investment. That changes deal

dynamics, deal size, and who signs the purchase order. Use the value calculator in the Deal Acceleration Kit to build customer-specific business cases.

Key discovery questions for the economic conversation:

- "What is the average cost of a P1 incident in your organisation today, including engineering time, revenue impact, and regulatory reporting?"
- "What proportion of your operations team's time is spent on repetitive, manual tasks rather than proactive improvement?"
- "How many experienced SREs or operations engineers have you lost to attrition in the last twelve months?"
- "Can you quantify your regulatory fine exposure under DORA/NIS2 for operational governance gaps?"
- "What is the ratio of reactive to proactive work in your operations organisation today?"
- "How many separate monitoring consoles do your operations teams use during a major incident?"

---

2. Market Sizing and Target Segments

2.1 Primary Segments

Financial Services. Banks, insurers, asset managers, payment processors, and market infrastructure operators. DORA compliance is the immediate catalyst, but the underlying drivers—multi-cloud complexity, real-time transaction monitoring, cross-border operations—are structural. Financial services organisations are typically the most advanced in their cloud adoption and the most acute in their awareness of operational sovereignty gaps. They have the budget, the regulatory motivation, and the technical maturity to act. Deal sizes in this segment range from USD 500K for an initial observability deployment to USD 5M+ for a full sovereign operations platform.

Public Sector and Government. National and regional government agencies, defence organisations, and public-sector digital services. Data-residency requirements, national security considerations, and public accountability obligations create a natural fit for sovereign operations. The challenge is procurement complexity and longer sales cycles. Government deals often require on-premises or sovereign-cloud deployment (IBM Cloud for Government, air-gapped environments). Deal sizes range from USD 300K for departmental deployments to USD 10M+ for national-scale platforms.

Healthcare and Life Sciences. Hospital groups, health insurers, pharmaceutical companies, and clinical research organisations. Patient data sovereignty under HIPAA (US), GDPR (EU), and national health data regulations drives the requirement. The clinical safety dimension—operational failures that affect patient care—adds urgency that pure commercial considerations do not. Deal sizes range from USD 250K to USD 3M.

Telecommunications. Mobile operators, fixed-line providers, and network equipment vendors. Telecoms operators manage some of the most complex operational estates in the world: millions of network elements, real-time service assurance requirements, and regulatory obligations around emergency services and lawful intercept. They are also among the most aggressive adopters of AI-driven operations (often under the banner of "autonomous networks"). Deal sizes range from USD 500K to USD 8M.

Energy and Utilities. Power generation, grid operators, oil and gas, and water utilities. Operational technology (OT) convergence with IT, critical national infrastructure obligations, and NIS2 compliance create the requirement. The OT dimension adds complexity—many operational tools do not extend into industrial control system environments—but it also creates a defensible position for IBM, given the breadth of the portfolio. Deal sizes range from USD 300K to USD 5M.

2.2 Buying Signals

Not every organisation with multi-cloud infrastructure is ready to buy sovereign operations capabilities. Look for these signals that indicate active pain and budget authority:

Signal	What It Tells You	Next Step
Active DORA/NIS2 compliance programme	Regulatory deadline creates urgency and budget	Map IBM capabilities to specific regulatory requirements
Recent major incident with board visibility	Pain is fresh, political capital exists for investment	Lead with AIOps incident correlation and MTTR reduction
Cloud migration or modernisation programme	Operational complexity is about to increase sharply	Position sovereign operations as a prerequisite, not an afterthought
Multiple monitoring tool consolidation initiative	Customer recognises tool sprawl is a problem	Lead with Instana + Concert as a consolidation play
Operations team attrition above industry average	Talent retention is a C-suite concern	Position automation as a retention strategy
Upcoming regulatory audit or examination	Time-bound compliance pressure	Lead with governance and audit trail capabilities
Board or C-suite discussion of operational resilience	Strategic priority, not just IT plumbing	Engage at CxO level with the sovereignty narrative
Multi-cloud strategy formalisation	Customer is acknowledging the operational challenge	Position the cross-cloud control plane as essential infrastructure
Failed or underperforming AIOps PoC with a competitor	Disillusionment creates openness to a different approach	Lead with Concert's topology-aware correlation as the differentiator
Merger or acquisition activity	Estate complexity is about to double	Position sovereign operations as integration accelerator

WIIFM: These buying signals tell you when to invest your time. A customer exhibiting three or more of these signals is an active opportunity. One signal is a nurture conversation. Zero signals means qualify out and move on. Your pipeline quality improves when you focus on customers who are already feeling the pain.

Part II — The IBM Portfolio for Sovereign Operations

3. The Four-Plane Reference Architecture

Before positioning individual products, establish the architectural frame. Sovereign cloud operations is organised into four planes, each addressing a distinct concern:

Plane	Concern	Key Capabilities	IBM Technology
Observability Plane	Seeing everything	Metrics, traces, logs, topology discovery, real-time health scoring	IBM Instana
Automation & Orchestration Plane	Acting on what you see	Infrastructure as code, GitOps, runbook execution, resource optimisation	IBM Turbonomic, Ansible Automation Platform

Plane	Concern	Key Capabilities	IBM Technology
Agentic Intelligence Plane	Thinking about what you see	AI correlation, causal analysis, conversational operations, multi-agent coordination	IBM Concert, watsonx Orchestrate
Governance & Audit Plane	Proving what you did	Policy-as-code, immutable audit trails, AI governance, regulatory mapping	watsonx.governance, IBM Concert

Why the four-plane model matters for selling. It gives you a structured way to have the discovery conversation. Instead of asking "what monitoring tools do you use?"—which invites a defensive response—you can ask "how mature is each of these four capabilities in your estate today?" That question opens a gap analysis conversation that naturally leads to the IBM portfolio.

The four-plane model also addresses the "point product versus platform" objection. Each plane can be adopted independently, but the value compounds when they work together. Instana feeds telemetry to Concert, which correlates it and generates recommendations; Orchestrate executes those recommendations with human approval gates; watsonx.governance provides the audit trail that proves the entire chain was governed. The integration is the value proposition.

The zero-copy integration principle. The architecture is designed so that telemetry and operational data need not be duplicated across sovereign zones. Instead, queries travel to the data—the observability plane federates queries across zone-local stores, and the governance plane logs actions at the zone where they occur. This is not merely a performance optimisation; it is a sovereignty requirement. Data that crosses zone boundaries is data that may violate residency obligations. Zero-copy integration keeps sovereign data in its zone whilst still enabling cross-zone operational visibility.

Addressing the meta-lock-in concern. Sophisticated customers will ask whether adopting the full IBM sovereign stack merely substitutes IBM lock-in for hyperscaler lock-in. The answer is architectural: each plane relies on open standards and interface contracts (OpenTelemetry for observability, Ansible and Terraform for automation, OCI for containers, OIDC for identity) that make individual components substitutable. The architecture includes documented exit paths for each component. Strategic optionality is an explicit design requirement, not an afterthought. When a customer raises this concern, welcome it—it demonstrates architectural maturity and creates an opportunity to differentiate IBM from competitors who cannot make the same claim.

> **WIIFM:** The four-plane model is your whiteboard framework. Draw it in the first meeting. It positions you as an architect, not a product salesperson. Customers who engage with the model sell themselves on the portfolio because they can see where their gaps are. It also gives you four separate entry points for the conversation—and four separate deal components for deal structuring.

---

4. Product Positioning

4.1 IBM Instana — The Observability Foundation

What it does. Instana provides automatic, full-stack observability across the entire application estate: infrastructure, containers, Kubernetes, serverless, databases, messaging systems, and custom applications. It auto-discovers topology, automatically instruments applications, and provides real-time health scoring without requiring manual configuration or agent tuning.

Key capabilities for sovereign operations:

- **Automatic discovery and instrumentation.** Instana's agent discovers infrastructure components, middleware, and application services automatically, building a continuously updated dependency map. In a multi-cloud estate, this eliminates the manual effort of maintaining a CMDB and ensures that the operational picture reflects reality rather than a stale configuration document. New services, containers, and dependencies appear in the topology within seconds of deployment.

- **Distributed tracing.** Every transaction is traced end-to-end across service boundaries, cloud boundaries, and technology stacks. When a user-facing service degrades, Instana shows the exact call chain, the latency at each hop, and the component where the bottleneck or error occurs. This is not sampling-based—Instana captures every trace, which matters in regulated environments where the problematic transaction may be the one a sampler would have discarded.
- **Real-time health scoring.** Instana computes health scores for every component and service continuously, not on a polling interval. Health scoring incorporates error rates, latency percentiles, saturation metrics, and anomaly detection against learned baselines. These scores feed directly into Concert's correlation engine, providing the signal quality that makes AI-driven incident correlation accurate.
- **Kubernetes and OpenShift depth.** Instana provides deep visibility into Kubernetes clusters, including pod scheduling, resource requests and limits, horizontal pod autoscaler behaviour, and network policies. For organisations running Red Hat OpenShift—a common IBM customer profile—this integration is particularly valuable.
- **Open standards alignment.** Instana supports OpenTelemetry natively, which means it can ingest telemetry from applications instrumented with OpenTelemetry SDKs and can export data to other OpenTelemetry-compatible backends. This addresses the lock-in concern directly: customers are not committing to a proprietary instrumentation format.
- **Zone-aware deployment.** Instana agents and backends can be deployed within sovereign zones, with telemetry remaining zone-local. The Instana backend supports federated queries across zone-local installations, enabling cross-zone visibility without cross-zone data movement—the zero-copy principle in practice.

Deployment models:

- SaaS (IBM Cloud-hosted, multi-tenant)
- Dedicated SaaS (single-tenant, customer-selected region)
- Self-hosted on OpenShift (on-premises or customer-managed cloud)
- Air-gapped (for classified or highly regulated environments)

Integration patterns:

- Feeds telemetry to IBM Concert for AI-driven correlation
- Integrates with Turbonomic for resource optimisation decisions based on real-time performance data
- Exports to third-party SIEM and log aggregation platforms via OpenTelemetry and native integrations
- Integrates with ServiceNow, PagerDuty, and Slack for alert routing

Discovery questions:

- "How long does it take your team to determine the root cause of a cross-service incident today?"
- "How many monitoring tools do your engineers navigate during a P1 incident?"
- "When a new microservice is deployed, how long before it appears in your monitoring? Is that automatic or manual?"
- "Can you trace a single transaction from the user's browser through every service and database it touches?"
- "How confident are you that your topology map reflects the actual state of your estate right now?"

Competitive positioning versus Datadog, Dynatrace, Splunk, and New Relic:

Dimension	IBM Instana	Competitors
Instrumentation model	Automatic, no code changes required	Varies; many require manual SDK integration or code annotations
Trace capture	Every trace, no sampling	Typically sample-based (1–10% in production)
Deployment flexibility	SaaS, dedicated, self-hosted, air-gapped	Most are SaaS-only or SaaS-primary; self-hosted options limited

Dimension	IBM Instana	Competitors
OpenTelemetry	Native support, bidirectional	Varies; some treat OTel as ingest-only
Sovereign zone support	Zone-local backends with federated query	Generally centralised; limited multi-tenancy for sovereignty
IBM Concert integration	Native, real-time feed	Requires custom integration or not supported

> **WIIFM:** Instana is the door-opener for the sovereign operations conversation. Most customers already have monitoring tools but are dissatisfied with the number of tools, the manual effort to maintain them, and the inability to get a cross-cloud picture. Lead with the automated discovery and cross-cloud topology story. Once Instana is deployed, you have telemetry flowing—and that telemetry is the prerequisite for selling Concert, Turbonomic, and the rest of the stack. Instana lands typically range from USD 150K to USD 500K ARR, with expansion as coverage grows.

Configuration considerations for sovereign deployments:

When deploying Instana in a sovereign operations context, several configuration decisions are architecturally significant:

- **Backend topology.** Each sovereign zone requires its own Instana backend for zone-local telemetry retention. The backends are configured for federated query, allowing cross-zone visibility without data movement. The federation layer queries each backend in parallel and assembles a unified result set, with the query itself carrying zone-authorisation metadata that determines which backends will respond.
- **Agent deployment.** Instana agents are deployed as DaemonSets on Kubernetes/OpenShift clusters and as host agents on traditional infrastructure. Agent-to-backend communication is encrypted (mTLS) and can be routed through zone-local proxies to prevent telemetry leaving the zone boundary even in transit.
- **Custom service mapping.** While Instana auto-discovers most services, organisations can define custom service mappings that group components into business-meaningful services. This is particularly important for the Concert integration: Concert's health scoring and business-impact assessment depend on understanding which components constitute a business service.
- **Alert configuration.** Instana's built-in alerting is typically supplemented by Concert's situation management for production deployments. However, Instana alerts remain valuable for component-level monitoring and for environments where Concert is not yet deployed. Instana supports smart alerting with dynamic baselines, which reduces false positives compared to static threshold-based alerting.
- **Retention and archival.** Instana's retention policies should be aligned with the organisation's regulatory retention requirements. For DORA-regulated environments, incident-related telemetry may need to be retained for five years. Instana supports configurable retention periods and can export historical data to long-term storage.

4.2 IBM Turbonomic — Resource Optimisation and Automation

What it does. Turbonomic continuously analyses application resource consumption and automatically right-sizes infrastructure—compute, storage, and network—to ensure performance whilst minimising waste and cost. It treats resource allocation as an economic problem: matching supply to demand in real time, across cloud and on-premises environments.

Key capabilities for sovereign operations:

- **Application-aware resource management.** Turbonomic does not optimise infrastructure in isolation; it understands the relationship between application performance and resource allocation. It will not reduce a VM's CPU allocation if doing so would breach the application's response-time

SLO. This application awareness distinguishes Turbonomic from cloud-native cost optimisation tools that operate at the infrastructure layer without understanding application impact.

- **Continuous optimisation, not periodic reports.** Unlike cost management tools that produce monthly reports of waste, Turbonomic generates actionable resize, scale, and placement recommendations continuously. Recommendations can be executed automatically (for approved categories), scheduled for maintenance windows, or presented for human approval—matching the progressive autonomy model that sovereign operations requires.
- **Cross-cloud placement.** Turbonomic can recommend workload placement across clouds based on cost, performance, and policy constraints. In a sovereign operations context, policy constraints include zone-residency requirements: certain workloads must remain in certain zones regardless of cost optimisation opportunities.
- **Reserved instance and savings plan optimisation.** Turbonomic analyses consumption patterns and recommends optimal reserved instance purchases across AWS, Azure, and GCP, taking into account existing commitments, consumption variability, and projected growth.
- **Integration with Concert and Instana.** Turbonomic's resource recommendations feed into Concert's overall operational picture. When Concert identifies a performance degradation, it can correlate it with Turbonomic's resource data to determine whether the root cause is a resource constraint that Turbonomic can resolve, or an application-level issue that requires a different remediation path.

Deployment models:

- SaaS (IBM Cloud-hosted)
- Self-hosted on Kubernetes/OpenShift (on-premises or customer-managed cloud)

Discovery questions:

- "What percentage of your cloud compute capacity is utilised on average? How do you know?"
- "When was the last time you right-sized a production workload? What was the process?"
- "How do you balance cost optimisation with performance risk? Who makes that trade-off decision?"
- "Do you have visibility into reserved instance utilisation across all your cloud accounts?"
- "How much do you spend annually on cloud infrastructure that is provisioned but underutilised?"

Competitive positioning versus CloudHealth, Apptio, and cloud-native tools (AWS Cost Explorer, Azure Cost Management):

Dimension	IBM Turbonomic	Competitors
Optimisation approach	Application-aware, real-time, automated	Typically infrastructure-only, periodic, advisory
Action execution	Can automate resize/scale within approved bounds	Mostly reporting; action requires manual steps
Cross-cloud scope	AWS, Azure, GCP, on-premises, OpenShift	Cloud-native tools see only their own platform
Performance risk awareness	Will not optimise if it risks SLO breach	Cost-focused; performance impact is the customer's risk
Sovereignty integration	Respects zone placement policies; feeds Concert	No sovereignty awareness

> **WIIFM:** Turbonomic sells itself with a financial story. If the customer is spending USD 10M per year on cloud infrastructure, Turbonomic typically identifies 20–30% waste within the first 30 days. That is a USD 2–3M annual saving against a Turbonomic investment of USD 200–500K. The ROI conversation is straightforward and self-funding. Start with a 30-day proof of value; the data does the selling. Turbonomic lands typically range from USD 200K to USD 600K ARR.

Turbonomic in the autonomous operations context:

Turbonomic's automation capabilities align directly with the progressive autonomy model. At Level 1, Turbonomic generates advisory reports that operators review and act on manually. At Level 2,

Turbonomic recommendations are presented through Orchestrate for operator approval before execution. At Level 3, Turbonomic executes approved optimisation categories automatically—right-sizing non-production VMs, adjusting storage tiers, purchasing reserved instances within pre-approved budgets—with human oversight restricted to exception review. This progression mirrors the broader sovereign operations maturity journey and provides a natural expansion path within the Turbonomic deployment.

The integration with Concert adds a performance-safety dimension. Before Turbonomic executes a resize action, Concert evaluates whether the target component is currently involved in an active situation or is exhibiting health anomalies that would make the optimisation risky. If Concert flags elevated risk, Turbonomic defers the action or escalates it for human approval, even if the action category is normally automated. This Concert-Turbonomic feedback loop is a concrete example of cross-plane integration that no single-product competitor can replicate.

> **WIIFM:** When presenting Turbonomic to a CFO or FinOps lead, frame it as a financial instrument, not a technology tool. "Turbonomic is a continuous optimisation engine that ensures you are paying for only the cloud resources your applications actually need, without risking performance. It is not a report; it is an autopilot for cloud spend." The 30-day proof of value is your strongest selling motion across the entire portfolio—it costs almost nothing, generates hard data, and the savings story practically writes the business case. Close rates from Turbonomic PoV to purchase exceed 60% industry-wide.

4.3 IBM Concert — The Operational Brain

What it does. Concert is the AIOps engine that correlates signals from across the operational estate—metrics, logs, traces, change events, topology data—against a live application dependency model and surfaces prioritised, evidence-backed recommendations for remediation, optimisation, and risk mitigation.

Key capabilities for sovereign operations:

- **Typed entity graph.** Concert continuously discovers and maintains a typed entity graph of services, deployments, infrastructure components, and their dependencies. This is not a static CMDB; it is a live, automatically updated model of the application estate that reflects reality within seconds of a change. The entity graph is the foundation for all of Concert's analytical capabilities—without an accurate topology, correlation is guesswork.
- **Signal correlation and situation management.** Concert ingests alerts, anomaly detections, and events from dozens of sources (Instana, Turbonomic, hyperscaler-native tools, third-party monitors) and correlates related signals into *situations*—unified representations of what appears to be a single operational problem. A single infrastructure fault that generates 47 alerts across three monitoring tools becomes one Concert situation with a severity score, a probable root cause, and a recommended remediation path. Operators engage with situations, not alerts, dramatically reducing cognitive overhead.
- **Causal inference.** Concert's correlation engine combines graph-based reasoning (traversing the dependency graph to identify causal chains) with historical pattern matching (comparing current signal patterns against past incidents) to surface probable root causes. The output is not a guess; it is an evidence-backed hypothesis with a confidence score and supporting data.
- **Health scoring and recommendation generation.** Concert computes dynamic health scores for every entity in its graph and generates prioritised recommendations when health scores degrade or risk conditions are detected. Recommendations include the evidence that supports them, the affected components, the blast radius of the proposed action, and the risk classification that determines which response mode applies.
- **Three response modes.** Concert recommendations flow through one of three response modes: human-initiated (operator decides and acts), agent-assisted (watsonx Orchestrate elaborates a multi-step plan for operator approval), or automated (pre-approved playbook executes without per-instance approval). The response mode is determined by action risk classification based on blast radius, reversibility, historical failure rate, and current system health. This classification is dynamic—an action that is normally automated may be escalated to human-initiated if Concert detects elevated system stress.

- **Change risk scoring.** Before a planned change—a deployment, a configuration update, a scaling event—Concert evaluates it against current estate health and produces a composite risk score reflecting blast radius, historical change failure rate, current component health, and calendar context. This score integrates into CI/CD pipelines via Concert's change risk API, enabling teams to make evidence-based deployment decisions.
- **Sovereign zone awareness.** Concert's entity graph, correlation engine, and recommendation system are all zone-aware. Recommendations respect zone boundaries; data does not cross zones; and zone-specific governance policies constrain what actions can be recommended or automated within each zone.
- **Bidirectional ITSM integration.** Concert synchronises with ServiceNow and other ITSM platforms bidirectionally: situations create incidents, severity changes are reflected, resolution status is synchronised, and change risk scores are written back to change requests. This eliminates the dual-maintenance problem where operations teams must update both their AIOps platform and their ITSM system of record.

Deployment models:

- SaaS (IBM Cloud-hosted)
- Self-hosted on OpenShift (on-premises, customer-managed cloud, air-gapped)

The four canonical AIOps workflow patterns:

1. **Incident correlation and triage** — grouping related alerts into situations, assigning severity based on business impact, surfacing root cause hypotheses
2. **Change risk assessment** — scoring planned changes against current estate health and historical failure rates
3. **Capacity and cost optimisation** — identifying persistent underutilisation, projected shortfalls, and cost anomalies
4. **Proactive risk identification** — scanning for conditions that have not yet caused incidents but are likely to (expiring certificates, memory leaks, deprecated API dependencies)

Discovery questions:

- "When a major incident occurs, how long does it take to determine which business services are affected?"
- "How many alerts does your team receive during a typical major incident? How many of those are duplicates or symptoms of the same underlying fault?"
- "Do you have a single view of application dependencies across all your clouds, or does each team maintain its own understanding?"
- "How do you assess the risk of a deployment before it happens? Is that assessment based on evidence or intuition?"
- "Can you demonstrate to a regulator exactly what happened during an incident—who was notified, what was decided, what was executed, and when?"
- "What is your current change failure rate, and do you track it systematically?"

Competitive positioning versus ServiceNow IT Operations Management, Splunk ITSI, BigPanda, and Moogsoft:

Dimension	IBM Concert	Competitors
Topology model	Live, auto-discovered entity graph	Typically relies on CMDB (static, often stale)
Correlation approach	Graph + historical pattern + real-time health	Primarily rule-based or statistical clustering
Sovereign zone awareness	Native, architecture-level	Typically absent; centralised by design
Change risk scoring	Composite, dynamic, CI/CD-integrated	Limited or absent
Response modes	Three modes with dynamic risk classification	Typically alert forwarding to ITSM

Dimension	IBM Concert	Competitors
Orchestrate integration	Native handoff to agentic execution	Manual handoff to separate automation tools

> **WIIFM:** Concert is the centre of the sovereign operations deal. It is where the AI story becomes tangible: "Concert correlated 47 alerts into one situation and identified the root cause in 90 seconds; your team currently takes 45 minutes." That specificity wins deals. Concert sits at the intersection of AIOps, regulatory compliance, and operational efficiency—three budget lines, not one. Concert deals typically range from USD 300K to USD 1.5M ARR, and they pull Instana (as the telemetry source) and Orchestrate (as the action layer) into the deal.

Concert measurement framework for customer conversations:

Five metrics provide the core framework for measuring Concert's operational impact. Use these in customer conversations to establish measurable success criteria for proof of concepts and to demonstrate value post-deployment:

1. **Recommendation acceptance rate** — the proportion of Concert recommendations acted on by operators. Target: above 80%. A declining rate signals recommendation quality issues that need attention.
2. **Mean time from situation creation to resolution** — the primary measure of Concert's impact on incident response speed. Baseline before deployment, trend over time, segment by severity.
3. **Change failure rate trend** — the proportion of deployed changes resulting in incidents or rollbacks. Concert's change risk scoring should drive a measurable downward trend within 6 months.
4. **False positive rate** — the proportion of Concert situations that turn out not to represent genuine problems. Target: below 15%. Above this threshold, operator trust erodes.
5. **Operator escalation rate** — how often automated or agent-assisted actions are escalated to human review. A high initial rate declining over weeks is normal and healthy as operators build confidence.

These metrics are not just operational measures; they are sales tools. When a customer can see that Concert reduced their MTTR by 50% and their change failure rate by 25%, the renewal and expansion conversations become straightforward.

Concert's proactive risk identification in practice:

Concert's most analytically demanding capability is proactive risk identification: scanning the estate for conditions that have not yet caused incidents but that historical data, topology analysis, and model-based reasoning suggest are likely to do so. Examples include: a certificate approaching expiry that has not yet triggered an alert but will breach SLO thresholds within the planning horizon; a gradual memory leak whose current trajectory will exhaust headroom before the next maintenance window; a dependency on a deprecated API version scheduled for removal in an upstream service update. Concert surfaces these findings with evidence and urgency scores, routing them as scheduled recommendations rather than reactive incidents. Organisations that act on proactive recommendations are managing risk rather than managing failures—a distinction that resonates strongly with CRO and CISO personas.

4.4 IBM watsonx Orchestrate — Conversational Operations

What it does. Orchestrate is a conversational and workflow engine that translates natural-language operator intent into sequences of authenticated, logged tool calls. It bridges the gap between Concert's recommendations and the multi-tool actions required to execute them, providing a single interface that abstracts the tool estate and produces a structured audit trail as a natural by-product of operation.

Key capabilities for sovereign operations:

- **Five-layer architecture.** Language model (understands operator intent), tool registry (catalogue of callable capabilities), workflow engine (multi-step operations with approval gates), memory (conversational continuity), governance integration (identity, approval, monitoring). Each layer

is configurable to meet deployment constraints, including sovereign-zone requirements for where language model inference runs.

- **Tool-calling model.** Orchestrate translates natural-language requests into structured tool invocations against a typed registry. The registry acts as a policy boundary: only approved tools can be called, and zone-scoped registries ensure that tools respect sovereign-zone boundaries. Tool authentication uses short-lived, scoped credentials from the identity fabric—no long-lived secrets are stored.
- **YAML-defined workflows.** Multi-step operations (e.g., TLS certificate renewal: check status, generate CSR, submit to CA, approve, deploy, verify, close change record) are defined as YAML flow definitions with sequential steps, parallel fan-outs, conditional branches, and mandatory approval gates. Flow definitions are version-controlled in Git and subject to the same change-management controls as infrastructure code.
- **Approval gates.** At defined points in a workflow, execution pauses and presents the operator or a nominated approver with a structured summary of what is about to happen. Approval decisions are logged with identity and timestamp. Gates can be configured to require specific roles, expire after defined intervals, and escalate if the primary approver does not respond.
- **Multi-agent coordination.** Orchestrate functions as the planner agent in a multi-agent architecture, decomposing complex tasks and delegating to specialised agents (security scanning, cost analysis, Kubernetes operations) through its tool registry. All agent-to-agent communication flows through Orchestrate's conversation context, ensuring visibility and governance.
- **Conversation as audit trail.** Every turn in an Orchestrate conversation is timestamped, attributed to the authenticated operator, and linked to the tool calls made on their behalf. The conversation log is a compliance artefact: it answers "who authorised what, when, with what evidence, and what happened" in a form that both humans and automated audit tools can read.
- **Pre-built integrations.** Concert query tools, Ansible Automation Platform, Terraform, ServiceNow, GitHub/GitLab, Kubernetes—covering the most common operational domains. Extensible via the tool skill editor, OpenAPI import, and Python/JavaScript SDK.

Deployment models:

- SaaS (IBM Cloud-hosted)
- Self-hosted on OpenShift (on-premises, customer-managed cloud, air-gapped)—critical for sovereign-zone deployments where language model inference must remain within jurisdiction

Discovery questions:

- "How many separate tools does an operator touch to execute a standard remediation workflow from detection to resolution?"
- "When a regulator asks 'who authorised this change and what exactly happened,' how long does it take to reconstruct the answer?"
- "Do your operators have a single interface for operational actions, or do they context-switch between multiple consoles?"
- "How do you ensure that automated actions respect zone boundaries and require appropriate approvals?"
- "What proportion of your runbooks are executable versus documentation that operators interpret and translate into manual steps?"

WIIFM: Orchestrate is the "wow factor" in a customer demo. When an operator types a natural-language request and watches a multi-step, multi-tool operation unfold with proper approvals and a complete audit trail—all in under five minutes for what previously took 45–120 minutes manually—the value is viscerally obvious. Orchestrate also has a strong standalone story for AI-driven workflow automation beyond the sovereign operations context. Orchestrate lands typically range from USD 200K to USD 800K ARR.

4.5 IBM Ansible Automation Platform — Governed Execution

What it does. Ansible Automation Platform (AAP) provides the execution layer for operational automation: playbooks that translate Concert recommendations and Orchestrate workflow steps into concrete, idempotent, auditable actions on infrastructure. It is the "hands" of the sovereign operations platform—the component that actually touches systems.

Key capabilities for sovereign operations:

- **Idempotent execution.** Ansible playbooks describe desired state, not procedural steps. Running a playbook twice produces the same result, which makes automated remediation safe: if a Concert recommendation triggers a playbook that has already been applied, the playbook detects the current state and takes no action.
- **Event-driven automation.** Ansible's Event-Driven Automation (EDA) capability enables playbooks to fire in response to events from Concert, Instana, or other monitoring sources, enabling closed-loop remediation for pre-approved, low-risk action categories.
- **Inventory and credential management.** AAP manages inventories (which systems a playbook can target) and credentials (how it authenticates) centrally, with role-based access control. Zone-scoped inventories ensure that a playbook targeting one sovereign zone cannot inadvertently execute against another.
- **Execution environments.** Containerised execution environments ensure that playbooks run with consistent, auditable dependencies regardless of where they execute. This eliminates the "works on my machine" problem for operational automation.
- **Audit trail.** Every playbook execution is logged: who triggered it, what parameters were used, which systems were affected, what changed, and what the outcome was. These logs feed into the governance plane and integrate with ITSM platforms for regulatory traceability.

Deployment models:

- Self-hosted on OpenShift or standalone Linux
- Managed service on IBM Cloud

Discovery questions:

- "What proportion of your operational runbooks are automated today versus manually executed?"
- "How do you ensure that automated changes are restricted to the correct environments and zones?"
- "Do you have a consistent execution environment for automation, or does it depend on which engineer is running it?"
- "Can you demonstrate to a regulator that every automated action was authorised, logged, and executed with the correct credentials?"

  WIIFM: Ansible is often already in the customer's estate. If they are using Ansible Community (open source) without AAP, the upgrade to AAP—with its RBAC, audit logging, and execution environments—is a natural sell in the context of sovereign operations governance. If they are using a competing automation platform (Puppet, Chef, Terraform alone), the Concert-to-AAP integration is a differentiation point. AAP deals typically range from USD 100K to USD 500K ARR.

4.6 IBM watsonx.governance — AI Governance and Model Monitoring

What it does. watsonx.governance provides the governance layer for AI systems, including the language models used by Concert and Orchestrate. It monitors model behaviour, detects drift and anomalies, enforces compliance policies, and provides the audit evidence required by frameworks such as the EU AI Act and NIST AI RMF.

Key capabilities for sovereign operations:

- **Model behaviour monitoring.** Continuous tracking of how language models interpret operator requests and select tools, with alerting when behaviour drifts from expected patterns.

- **Bias and fairness monitoring.** Detection of systematic patterns in how AI-driven recommendations are generated across different user groups, system types, or zones.
- **Explainability.** Documentation of how specific recommendations or decisions were generated, supporting the transparency requirements of the EU AI Act.
- **Compliance mapping.** Pre-built templates mapping governance controls to specific regulatory requirements (EU AI Act, NIST AI RMF, sector-specific AI regulations).
- **Lifecycle management.** Tracking of model versions, training data provenance, and deployment history across the AI estate.

Discovery questions:

- "If a regulator asks how your AI operations tools make decisions, can you explain the reasoning behind a specific recommendation?"
- "How do you monitor whether your AI systems are behaving consistently over time?"
- "Do you have a governance framework for the AI systems used in your operations, or are they treated as black boxes?"
- "How do you satisfy EU AI Act obligations for AI systems used in critical infrastructure?"

WIIFM: watsonx.governance is typically a smaller deal component (USD 50K–200K ARR) but it is strategically important. It addresses the "how do you govern the AI that governs your operations?" question that CISOs and risk officers will inevitably ask. Without watsonx.governance in the stack, the Concert and Orchestrate story has a governance gap. With it, you have a complete, auditable chain from telemetry to action to AI oversight.

4.7 Red Hat OpenShift — The Sovereign Platform

What it does. OpenShift is the Kubernetes platform on which the entire IBM sovereign operations stack can be deployed. It provides the consistent runtime environment that enables the same software to run on any cloud, on-premises, or in an air-gapped sovereign zone.

Key capabilities for sovereign operations:

- **Consistent runtime across environments.** The same OpenShift distribution runs on AWS, Azure, GCP, IBM Cloud, on-premises bare metal, and air-gapped environments. This consistency is the foundation for sovereign zone architecture: each zone runs the same platform, with the same APIs, the same security model, and the same operational tooling.
- **Operator framework.** OpenShift Operators (software, not people) automate the deployment, configuration, and lifecycle management of the IBM software stack. Installing Instana, Concert, Orchestrate, or Turbonomic on OpenShift is an Operator-managed process with consistent upgrade paths.
- **Security and compliance.** OpenShift provides built-in security features (Security Context Constraints, network policies, image signing and scanning, audit logging) that satisfy the platform-level security requirements of sovereign operations.
- **Hybrid cloud management.** Red Hat Advanced Cluster Management (RHACM) provides fleet management across OpenShift clusters in different clouds and zones, enabling consistent policy enforcement and lifecycle management.

Discovery questions:

- "Do you have a consistent container platform across all your clouds and data centres, or are you running different Kubernetes distributions in each environment?"
- "How do you ensure that software deployed in one zone cannot inadvertently access resources in another zone?"
- "What is your strategy for running the same operational tooling in a classified or air-gapped environment?"

WIIFM: OpenShift is often already in the customer's estate or on their roadmap. If it is, the sovereign operations stack deploys natively. If it is not, OpenShift becomes a platform deal that pulls the entire IBM software stack behind it. OpenShift platform deals range from USD 300K to USD 2M+ ARR. Position OpenShift as the sovereign platform, not just

a container runtime—it is the consistency layer that makes sovereignty technically achievable across heterogeneous infrastructure.

Part III — Sales Plays

5. Play 1: The Regulatory Compliance Play

Trigger: Customer has an active DORA, NIS2, or comparable regulatory compliance programme with a defined deadline and allocated budget.

Target persona: Chief Risk Officer, Chief Compliance Officer, Head of Operational Resilience, Head of IT Risk.

The conversation: "You have a regulatory deadline. The regulation requires you to demonstrate continuous operational governance—not just at audit time, but continuously. You need to show that every operational action across your multi-cloud estate is policy-governed, auditable, and attributable. You need to demonstrate that your incident detection and response is fast enough, your change management is evidence-based, and your AI systems are governed. How are you planning to demonstrate all of that today?"

Phased approach:

- **Phase 1 (Months 1–3): Assessment and quick wins.** Deploy Instana across a representative subset of the estate to establish observability baseline. Conduct a maturity assessment against the Sovereign Operations Maturity Model (SOMM) to identify the most critical governance gaps. Map specific regulatory requirements (e.g., DORA Article 11 on incident reporting, Article 12 on backup and recovery) to IBM capabilities. Deliverables: maturity assessment report, gap analysis, DORA/NIS2 capability mapping, Phase 2 investment case.
- **Phase 2 (Months 3–9): Core deployment.** Deploy Concert for AIOps correlation, situation management, and change risk scoring. Integrate Concert with the customer's ITSM platform (ServiceNow) for bidirectional synchronisation. Deploy Orchestrate for governed workflow execution with audit trails. Enable Concert's change risk API integration with CI/CD pipelines. Deliverables: operational Concert deployment, ITSM integration, change risk scoring in pipelines, governance dashboard.
- **Phase 3 (Months 9–15): Maturation and automation.** Progressively automate low-risk remediation categories using the progressive autonomy model. Deploy watsonx.governance for AI system monitoring. Conduct regulatory readiness assessment. Establish continuous compliance monitoring and evidence generation. Deliverables: automated compliance evidence generation, expanded automation coverage, regulatory readiness report.

Expected outcomes:

- 70–80% reduction in time to produce regulatory evidence (from manual assembly to automated generation)
- 40–60% reduction in MTTR through AI-driven incident correlation and triage
- Demonstrable audit trail for every operational action across the multi-cloud estate
- Change risk scoring integrated into deployment pipelines, reducing change failure rate by 20–30%

Deal structure: Three-phase engagement, typically USD 1–3M total contract value over 18–24 months. Phase 1 may be positioned as a fixed-fee consulting engagement (USD 50–100K) that funds the assessment and produces the investment case for Phases 2 and 3. Software licensing follows the phased deployment: Instana in Phase 1, Concert + Orchestrate in Phase 2, watsonx.governance in Phase 3. Services (IBM Expert Labs or Business Partner) for deployment, integration, and enablement.

Qualification criteria: Does the customer have an active regulatory programme with a named owner, a defined deadline, and allocated or allocable budget? If the answer to any of these is no, this is a nurture opportunity, not an active deal.

> **WIIFM:** Regulatory deals have the best close rates in the portfolio because the customer has an external deadline they cannot move and a penalty they cannot ignore. The deal is

not "should we invest in operations tooling?" but "how do we satisfy the regulator before the deadline?" That shifts the conversation from discretionary spend to mandatory compliance investment. These deals also have high expansion potential: once the platform is deployed for regulatory compliance, the operational efficiency and cost optimisation benefits become visible and drive additional investment.

Key competitive differentiators for the regulatory play:

When competing for regulatory compliance deals, emphasise these differentiators:

- **Bidirectional ITSM integration** — not just forwarding alerts to ServiceNow, but synchronising situations, severity, and resolution status in both directions. Most competitors offer unidirectional alert forwarding.
- **Change risk scoring in CI/CD pipelines** — Concert's change risk API integrates directly into delivery pipelines, providing per-change risk assessment that regulators can review. No competitor offers this natively.
- **Conversation-as-audit-trail** — Orchestrate's conversational interface produces a timestamped, attributed log of every operational action. This is a compliance artefact that no combination of separate tool logs can replicate.
- **Zone-aware architecture** — every component of the IBM stack understands sovereign zones and enforces zone boundaries. Competitors' centralised architectures cannot demonstrate zone-level governance to regulators.
- **Progressive autonomy with demotion triggers** — the ability to automatically demote an automated action category back to human-initiated if safety violations are detected. This addresses the regulatory concern that automation may bypass governance controls under operational pressure.

Seller tip: In the regulatory play, your most important internal resource is IBM Expert Labs' regulatory advisory capability. Engage them early to produce the DORA/NIS2 capability mapping that maps specific regulatory articles to specific IBM capabilities. This document is the most effective sales collateral in the regulatory play—it answers the customer's compliance team's questions directly and positions IBM as the vendor that understands the regulation, not just the technology.

---

6. Play 2: The AIOps Consolidation Play

Trigger: Customer has multiple disconnected monitoring and operations tools, is experiencing alert fatigue, and recognises that tool sprawl is increasing operational cost and risk.

Target persona: VP of IT Operations, Head of SRE, Platform Engineering Lead, CTO.

The conversation: "You have six monitoring tools producing thousands of alerts per day. Your team spends more time navigating between consoles and manually correlating signals than actually fixing problems. Every tool sees its own slice of the estate; none of them shows the cross-cloud dependency chain. When something breaks, you assemble a war room and start a manual investigation that takes 45 minutes before you even know what is affected. How much is that costing you—in engineering time, in incident duration, in talent burnout?"

Phased approach:

- **Phase 1 (Months 1–3): Observability consolidation.** Deploy Instana across the application estate to replace or augment fragmented monitoring tools. Establish a single topology view and health scoring baseline. Quantify current alert volumes, MTTR, and tool costs. Deliverables: consolidated observability deployment, baseline metrics, tool rationalisation roadmap.
- **Phase 2 (Months 3–6): AIOps overlay.** Deploy Concert to correlate signals from Instana and retained third-party tools. Configure situation management and implement ITSM integration. Demonstrate alert-to-situation compression ratios (typically 10:1 to 50:1). Deliverables: Concert deployment, situation management, measured compression ratios, MTTR improvement data.
- **Phase 3 (Months 6–12): Workflow automation.** Deploy Orchestrate for conversational operations. Automate the top 10 most common remediation workflows. Enable progressive autonomy for low-risk action categories. Deliverables: automated workflows, progressive autonomy configuration, operational efficiency metrics.

Expected outcomes:

- 80–95% reduction in alert volume through situation-based correlation (47 alerts become 1 situation)
- 40–60% reduction in MTTR through faster root cause identification
- 30–50% reduction in monitoring tool costs through consolidation
- Measurable improvement in operations team satisfaction and retention (reduced toil, more meaningful work)

Deal structure: Typically USD 500K–2M total contract value over 12 months. Instana may displace or augment existing tools, which creates a cost-offset story. Concert and Orchestrate layer on top. Services for integration and workflow definition.

Qualification criteria: Does the customer have four or more monitoring tools? Is MTTR for major incidents above 30 minutes? Has the customer expressed dissatisfaction with alert fatigue or tool sprawl?

> **WIIFM:** The AIOps consolidation play is your highest-volume play. Every enterprise with monitoring tool sprawl is a candidate. The proof point is the alert-to-situation compression ratio: when you can show that Concert compressed 200 alerts into 4 situations during a real-world test, the value is undeniable. This play also creates the platform from which all other plays (regulatory, cost optimisation, self-healing) are sold.

Handling the "we already have Datadog/Dynatrace" objection in the consolidation play:

The most common objection in this play is that the customer already has a primary monitoring tool and does not want to replace it. The response is not to position Instana as a replacement but to position Concert as the intelligence layer above:

"Your current monitoring tool is fine for what it does—monitoring its own scope. The problem is that you have five other scopes that it does not see, and when an incident crosses those boundaries, your team is back to manual correlation. Concert sits above all your monitoring tools—including the one you want to keep—and provides the cross-tool, cross-cloud correlation that no single monitoring tool can deliver. You keep what works; IBM adds what is missing."

In practice, many AIOps consolidation deals start with Concert (ingesting signals from existing tools) rather than Instana. Instana follows as the customer realises that the quality of Concert's correlation is limited by the quality of the signals it receives, and that Instana's auto-discovered topology and full-fidelity tracing provide significantly richer signal than the customer's existing tools.

> **WIIFM:** The AIOps consolidation play has the broadest addressable market because virtually every enterprise has monitoring tool sprawl. The key metric to lead with is alert-to-situation compression ratio—it is viscerally impressive and immediately understandable to technical and non-technical audiences alike. Ask the customer how many alerts they receive during a major incident, and then tell them that Concert typically compresses that by 10:1 to 50:1. That number opens wallets.

---

7. Play 3: The Cloud Cost Optimisation Play

Trigger: Customer is under pressure to reduce cloud infrastructure spend or improve cloud cost governance.

Target persona: CFO, VP of Infrastructure, Cloud Centre of Excellence Lead, FinOps Lead.

The conversation: "You are spending USD 15 million per year on cloud infrastructure across three providers. How much of that is waste? Not waste in theory—actual VMs running at 8% utilisation, reserved instances that expired and reverted to on-demand pricing, storage tiers that no one reviewed since the migration. Turbonomic can show you within 30 days. And unlike a cost report that tells you what to do and then sits on a shelf, Turbonomic can actually execute the optimisation—safely, automatically, with application performance protection."

Phased approach:

- **Phase 1 (30 days): Proof of value.** Deploy Turbonomic against the customer's estate in read-only mode. Generate a waste and optimisation report. Quantify specific savings opportunities with

application performance impact analysis. This phase is often offered at no cost or minimal cost as a proof of value. Deliverables: waste analysis report, savings quantification, performance risk assessment.

- **Phase 2 (Months 2–6): Approved optimisation.** Implement Turbonomic recommendations in approved categories (right-sizing, reserved instance optimisation, storage tiering). Track actual savings against projections. Expand coverage to additional environments and cloud accounts. Deliverables: implemented optimisations, tracked savings, expanded coverage.
- **Phase 3 (Months 6–12): Continuous automation.** Enable automated optimisation for approved categories with guardrails. Integrate Turbonomic with Concert for performance-aware capacity planning. Implement FinOps dashboards for ongoing governance. Deliverables: automated optimisation, Concert integration, FinOps governance.

Expected outcomes:

- 20–40% reduction in cloud infrastructure spend (typical range; results vary by estate maturity)
- ROI within 3–6 months (Turbonomic investment pays for itself from cost savings)
- Continuous optimisation replacing periodic manual reviews
- Application performance protection (no optimisation that risks SLO breach)

Deal structure: Turbonomic-led, typically USD 200K–600K ARR. The 30-day proof of value is the critical selling motion; the data from the PoV makes the business case for the customer. Often self-funding: the first year's savings exceed the first year's investment.

Qualification criteria: Is the customer spending more than USD 5M per year on cloud infrastructure? Is there a FinOps initiative or cloud cost reduction target? Is there CFO or CTO visibility on cloud spend?

> **WIIFM:** The cost optimisation play is the fastest path to a closed deal because the ROI is directly measurable and the proof of value is free. It is also the best expansion play: once Turbonomic is deployed, you have a platform relationship that opens the door for Instana, Concert, and the rest of the stack. The FinOps community is a growing buyer constituency; build relationships there.

The cost optimisation play as a platform entry point:

The cost optimisation play is strategically important beyond its own deal value because it is the lowest-friction entry point for the sovereign operations platform. Consider this typical expansion sequence:

1. **Month 1:** Turbonomic 30-day proof of value. No cost to the customer. Generates a savings report.
2. **Month 2:** Customer purchases Turbonomic based on the savings data. Turbonomic is deployed.
3. **Month 6:** Customer observes that Turbonomic's optimisation recommendations are most accurate when combined with real-time application performance data. Instana is proposed for application-aware optimisation.
4. **Month 9:** With Instana and Turbonomic deployed, the customer has observability and optimisation. The conversation naturally turns to "how do we use this data to reduce incident impact?" Concert is proposed.
5. **Month 12:** With Concert generating recommendations, the customer asks "can we automate the response?" Orchestrate and AAP are proposed.
6. **Month 18:** Full sovereign operations platform deployed. The initial USD 300K Turbonomic deal has expanded to a USD 2M+ platform deal.

This expansion sequence is not hypothetical; it is the most common path to a full sovereign operations platform deal. Start with the savings; end with the platform.

---

8. Play 4: The Autonomous Operations Play

Trigger: Customer wants to move from reactive operations (fighting fires) to proactive, increasingly autonomous operations (preventing fires).

Target persona: VP of Engineering, Head of SRE, CTO, Head of Platform Engineering.

The conversation: "Your operations team is stuck in reactive mode. They spend their days responding to alerts, manually executing runbooks, and producing compliance evidence. They want to do architecture, reliability engineering, and platform improvement—but they never have time because they are always fighting fires. What if 60% of those fires could be prevented or automatically remediated without human intervention? What would your team do with that time?"

Phased approach:

- **Phase 1 (Months 1–4): Observability and baseline.** Deploy Instana and Concert to establish full-stack observability and AIOps correlation. Measure current MTTR, alert volume, toil burden, and automation coverage. Conduct a maturity assessment using the Sovereign Operations Maturity Model. Deliverables: observability deployment, baseline metrics, maturity assessment.
- **Phase 2 (Months 4–9): Progressive automation.** Deploy Orchestrate and AAP for governed workflow execution. Automate the top 20 remediation workflows using the progressive autonomy model: start with human-initiated, promote to agent-assisted, then to automated as confidence builds. Implement Concert's proactive risk identification to surface conditions before they become incidents. Deliverables: automated workflows, progressive autonomy scorecard, proactive risk identification.
- **Phase 3 (Months 9–18): Self-healing operations.** Implement closed-loop remediation for approved action categories: Concert detects, diagnoses, and recommends; Orchestrate plans; AAP executes; Concert verifies. Establish autonomous action boundaries using the classification matrix of reversibility, blast radius, and regulatory sensitivity. Implement safety mechanisms: rate limiting, blast radius containment, automatic rollback, dead man's switch patterns, and escalation cascades. Deliverables: self-healing for approved categories, autonomous action boundary documentation, safety mechanism implementation, measured outcomes.

Expected outcomes:

- 60–80% of routine incidents auto-remediated within target MTTR
- 50–70% reduction in operations team toil burden
- Measurable improvement in team retention and satisfaction
- Progressive shift from Level 1 (Ad-hoc) to Level 3 (Proactive) or Level 4 (Optimised) on the Sovereign Operations Maturity Model
- Proactive identification of risk conditions before they cause incidents

Deal structure: Full-stack engagement, typically USD 1.5–5M total contract value over 18–24 months. This is the largest deal size in the portfolio because it involves the complete IBM sovereign operations stack. Phase 1 may be positioned as a smaller entry (USD 300–500K) with Phases 2 and 3 as expansion.

The progressive autonomy model in seller language:

The customer does not go from manual operations to autonomous overnight. The progression is deliberate and governed:

1. **Level 0 — Manual.** Human does everything. This is where most customers start.
2. **Level 1 — Advisory.** Concert recommends; human decides and acts. Concert reduces investigation time but does not act.
3. **Level 2 — Assisted.** Orchestrate elaborates a multi-step plan from Concert's recommendation; human reviews and approves; AAP executes. Human is in the loop for every action.
4. **Level 3 — Conditional automation.** For pre-approved, low-risk categories (restart a crashed pod, rotate an expiring certificate, scale within approved bounds), execution proceeds without per-instance approval. Human reviews outcomes retrospectively. Audit trail is maintained.
5. **Level 4 — Supervised autonomy.** Broader categories of action are automated, with dynamic escalation when Concert detects elevated risk. Human oversight focuses on exception management and governance rather than routine operations.

Each level requires demonstrated reliability at the previous level before promotion. Demotion triggers are asymmetric: a single safety violation demotes immediately, while promotion requires sustained performance over weeks.

Safety mechanisms for autonomous operations:

When presenting the autonomous operations play to risk-conscious customers, emphasise the safety mechanisms that make self-healing operations safe in regulated environments:

- **Rate limiting.** The system enforces maximum rates for automated actions per zone per time window. If an automated remediation generates a cascading series of follow-on actions, the rate limiter prevents runaway automation.
- **Blast radius containment.** Every automated action has a pre-calculated blast radius. Actions whose blast radius exceeds the configured threshold for the zone are automatically escalated to human approval, regardless of their risk classification.
- **Automatic rollback.** Automated actions that do not achieve their expected outcome within a configurable verification window are automatically rolled back. The rollback itself is an automated action with its own audit trail.
- **Dead man's switch.** For critical zones, a dead man's switch pattern requires periodic human acknowledgement that automated operations are proceeding correctly. If acknowledgement is not received within the configured interval, automated actions are suspended pending human review.
- **Escalation cascades.** When an automated action fails or is escalated, Concert triggers a notification cascade through defined channels (Slack, PagerDuty, email, phone) with escalation timeouts at each level. No automated failure goes unnoticed.

These safety mechanisms are not optional add-ons; they are architectural requirements for any autonomous operations deployment. Their presence is what distinguishes responsible AI-driven operations from reckless automation.

Cyber-resilient recovery patterns:

For customers concerned about cyber-resilience—the ability to recover from a ransomware attack or a comprehensive compromise—the autonomous operations play includes IBM Safeguarded Copy and cyber vault architecture patterns:

- **Safeguarded Copy** creates immutable, zone-local snapshots of critical data at scheduled intervals. These snapshots are stored in isolated storage that is not accessible from the production environment, ensuring that even a complete compromise of the production estate cannot corrupt backup data.
- **Cyber vault architecture** provides a hardened, isolated environment where backup integrity is validated against known-good signatures and where anomaly detection scans for indicators of compromise before restoration is attempted.
- **Clean room recovery** enables restoration of workloads into validated infrastructure when the production environment is compromised. Orchestrate manages the recovery workflow—validating backups, provisioning clean infrastructure, restoring services, and verifying application health—with full audit trail and approval gates.

These patterns map directly to DORA Article 12 requirements for backup and recovery, making them a compliance argument as well as a resilience argument.

Qualification criteria: Does the customer have an established SRE or platform engineering function? Is there executive sponsorship for operational transformation? Is the customer willing to invest in an 18+ month programme rather than a point product deployment?

> **WIIFM:** The autonomous operations play is the most strategically valuable deal in the portfolio. It commits the customer to the full IBM sovereign operations stack, creates a multi-year engagement, and positions IBM as the strategic operations partner rather than a software vendor. These deals generate the highest annual contract values and the strongest renewal rates. They also generate the most compelling reference stories for future deals.

---

9. Play 5: The Multi-Cloud Control Plane Play

Trigger: Customer has workloads on two or more public clouds plus on-premises and wants a single operational control plane.

Target persona: CTO, VP of Infrastructure, Cloud Architect, Head of Platform Engineering.

The conversation: "You run workloads on AWS, Azure, and on-premises. Each cloud has its own monitoring, its own identity system, its own compliance tools. Your operations team maintains three sets of runbooks, three sets of dashboards, and three mental models. When something breaks across cloud boundaries—and it will—you have no single view of what is happening. IBM provides the control plane that sits above all three, giving you unified observability, unified policy enforcement, and unified operational workflows. Not a replacement for your clouds—a layer that makes them manageable as one estate."

Phased approach:

- **Phase 1 (Months 1–3): Cross-cloud observability.** Deploy Instana agents across all clouds and on-premises environments. Establish the unified topology view. Demonstrate cross-cloud dependency tracking and health scoring. Deliverables: cross-cloud Instana deployment, unified topology map, cross-cloud tracing demonstration.
- **Phase 2 (Months 3–6): Cross-cloud intelligence.** Deploy Concert with collectors for each cloud environment. Configure cross-cloud situation correlation—demonstrate that an incident caused by a shared dependency is surfaced as one situation regardless of which clouds are affected. Integrate with the customer's existing ITSM platform. Deliverables: cross-cloud Concert deployment, cross-cloud correlation demonstration, ITSM integration.
- **Phase 3 (Months 6–12): Cross-cloud operations.** Deploy Orchestrate with zone-scoped tool registries for each cloud environment. Define cross-cloud workflows (e.g., failover from one cloud to another, coordinated scaling across clouds). Implement policy-as-code for cross-cloud governance. Deliverables: cross-cloud operational workflows, zone-scoped tool registries, policy-as-code framework.

Expected outcomes:

- Single operational view across all clouds and on-premises environments
- Cross-cloud incident correlation reducing investigation time by 50–70%
- Unified change management and risk assessment across clouds
- Consistent policy enforcement regardless of underlying platform

Deal structure: Typically USD 800K–3M total contract value over 12–18 months. The cross-cloud story justifies the platform investment because it addresses a capability that no single hyperscaler can provide.

> **WIIFM:** The multi-cloud control plane play is the most defensible competitive position in the portfolio. AWS cannot provide this for Azure workloads. Azure cannot provide this for AWS workloads. Only a vendor-neutral control plane can span the entire estate. When you demonstrate cross-cloud correlation—showing that an Azure DNS failure is affecting an AWS-hosted application through a shared API dependency—the value of the IBM control plane becomes self-evident.

---

10. Play 6: The Sovereign AI Governance Play

Trigger: Customer is deploying AI systems in operational or business contexts and needs a governance framework to satisfy regulatory requirements (EU AI Act, NIST AI RMF) or internal risk policies.

Target persona: Chief AI Officer, Chief Data Officer, Chief Risk Officer, Head of AI Ethics, CISO.

The conversation: "You are deploying AI across your operations and your business processes. The EU AI Act is in force. Your board wants to know: how are these AI systems governed? Can you explain how they make decisions? Can you demonstrate that they are monitored for drift, bias, and anomalous behaviour? Can you produce an audit trail that satisfies a regulatory examination? If the answer to any of these is 'not yet,' watsonx.governance is how you close the gap."

Phased approach:

- **Phase 1 (Months 1–2): AI inventory and risk classification.** Catalogue all AI systems in the operational and business estate. Classify each against EU AI Act risk tiers (minimal, limited, high,

unacceptable). Identify governance gaps. Deliverables: AI system inventory, risk classification, gap analysis.

- **Phase 2 (Months 2–6): Governance deployment.** Deploy watsonx.governance for monitoring of high-risk AI systems. Configure model behaviour tracking, drift detection, and explainability reporting. Establish governance dashboards for risk and compliance teams. Deliverables: watsonx.governance deployment, monitoring configuration, governance dashboards.
- **Phase 3 (Months 6–12): Continuous governance.** Integrate watsonx.governance with Concert and Orchestrate for operational AI governance. Establish ongoing compliance monitoring and evidence generation. Implement regulatory reporting automation. Deliverables: integrated AI governance, continuous compliance monitoring, regulatory reporting.

Expected outcomes:

- Complete AI system inventory with risk classification
- Continuous monitoring of AI model behaviour with anomaly alerting
- Regulatory-ready audit trails for all high-risk AI systems
- Demonstrable compliance with EU AI Act and NIST AI RMF

Deal structure: Typically USD 200K–800K total contract value over 12 months. Often combined with Concert and Orchestrate as part of a broader sovereign operations deal. The standalone AI governance deal is smaller but strategically important as a relationship builder with the CAIO/CDO persona.

> **WIIFM:** The AI governance play addresses a problem that every enterprise deploying AI will face within the next 12–24 months. The EU AI Act is not optional, and the penalties are material. Organisations that have already deployed AI systems without governance are particularly urgent targets. This play also opens the door to the broader watsonx platform conversation beyond the operations domain.

Part IV — Industry Plays

11. Financial Services

11.1 Regulatory Landscape

Financial services is the most regulated industry for operational resilience. The key frameworks are:

- **DORA (Digital Operational Resilience Act):** Applies to EU financial entities from January 2025. Requires ICT risk management frameworks, incident classification and reporting (within four hours for major incidents), digital operational resilience testing, and third-party risk management for cloud and ICT providers. Penalties up to 1% of average daily worldwide turnover.
- **PRA/FCA Operational Resilience (UK):** UK financial firms must identify important business services, set impact tolerances, and demonstrate they can remain within those tolerances through severe but plausible scenarios. Full compliance required from March 2025.
- **MAS Technology Risk Management Guidelines (Singapore):** Comprehensive requirements for technology risk governance, including cloud deployment, incident management, and operational resilience.
- **FFIEC (US):** Federal Financial Institutions Examination Council guidance on cloud computing, operational resilience, and third-party risk management.
- **Basel III Operational Risk:** Capital requirements for operational risk that incentivise investment in operational resilience.

11.2 Customer Pain Points

Financial services operations teams face specific challenges that the sovereign operations platform addresses:

Real-time transaction sovereignty. Payment processing, securities settlement, and market data distribution involve transactions that must complete within strict time bounds. Operational visibility into these flows requires millisecond-resolution tracing across multiple services, zones, and sometimes jurisdictions. Traditional monitoring tools that poll at 60-second intervals cannot detect the latency anomalies that precede a transaction processing failure.

Cross-border regulatory divergence. A European bank operating in the EU, UK, Switzerland, and Singapore faces four different regulatory regimes, each with different requirements for incident reporting, data residency, and operational governance. The sovereign operations platform must enforce zone-specific policies whilst providing a unified operational view across all jurisdictions.

DORA's ICT concentration risk. DORA requires financial entities to assess and manage the risk of excessive dependence on a single ICT third-party service provider. This creates a tension: organisations want the operational simplicity of a single cloud provider but the regulatory requirement pushes them toward multi-cloud. The sovereign operations control plane resolves this tension by making multi-cloud operationally manageable.

Payment system compliance. PCI-DSS, SWIFT CSP, and national payment system regulations impose specific controls on systems that process payment data. Operational actions on these systems require enhanced governance—additional approval gates, restricted access, enhanced audit trails—that must be enforced consistently regardless of the underlying cloud platform.

11.3 Solution Emphasis

- **Instana** for real-time, full-fidelity transaction tracing across payment processing chains (every trace, not sampled)
- **Concert** for DORA-compliant incident correlation, classification, and reporting (situation management with regulatory severity mapping)
- **Orchestrate** for governed remediation workflows with approval gates that satisfy change management requirements
- **Turbonomic** for capacity management that prevents performance degradation in latency-sensitive transaction processing
- **watsonx.governance** for governance of AI systems used in fraud detection, credit scoring, and algorithmic trading

11.4 Qualification Questions

- "How are you preparing for DORA compliance? Do you have a named programme with a defined timeline?"
- "Can you demonstrate to the regulator how you detect, classify, and report ICT-related incidents within the required timeframes?"
- "How do you manage operational governance across multiple regulatory jurisdictions?"
- "What is your current mean time to detect and respond to incidents affecting payment processing?"
- "How do you ensure that operational actions on PCI-scoped systems are properly governed and audited?"
- "Have you assessed your ICT concentration risk, and does your operational tooling support multi-cloud operations?"
- "What is your change failure rate for deployments to production financial systems?"

11.5 Solution Architecture Pattern for Financial Services

The typical financial services sovereign operations deployment follows this architecture pattern:

Zone design aligned to supervisory boundaries. A European bank operating under DORA will typically define sovereign zones aligned to regulatory supervisory jurisdictions: an EU zone (covering Eurozone operations), a UK zone (covering PRA/FCA-supervised operations), and additional zones for each non-EU jurisdiction where the bank operates. Each zone has its own Instana backend, Concert instance, and Orchestrate deployment, with telemetry remaining zone-local. Cross-zone visibility is provided through federated queries that do not move data.

Transaction tracing for payment systems. Instana is configured with custom service mapping that aligns technical components to business-meaningful payment processing chains. Each payment transac-

tion is traced end-to-end from the customer channel (mobile app, web portal, ATM) through the payment processing middleware, the core banking system, and the external payment network (SWIFT, SEPA, card scheme). Concert maps these traces to the payment processing service and assigns business-impact severity based on transaction volume and value.

Change risk scoring for financial system deployments. Concert's change risk API is integrated into the bank's CI/CD pipelines for all production deployments. High-risk changes (changes to core banking, payment processing, or regulatory reporting systems) require elevated approval and are scheduled outside peak transaction windows. Concert's calendar awareness includes financial quarter-ends, regulatory reporting deadlines, and high-volume payment processing periods.

Regulatory incident reporting. Concert's situation management is configured to map situation severity to DORA incident classification criteria. When a situation exceeds the severity threshold for a "major ICT-related incident" under DORA, Concert automatically generates the initial incident report in the format required for submission to the relevant supervisory authority and triggers the notification workflow.

11.6 Competitive Landscape

ServiceNow ITOM is the most common incumbent in financial services. The competitive differentiation is Concert's topology-aware correlation versus ServiceNow's CMDB-dependent approach (CMDBs in financial services are notoriously incomplete and stale), and Orchestrate's conversational workflow execution versus ServiceNow's form-based workflow builder. Datadog and Dynatrace are common for observability; differentiate on Instana's full-fidelity tracing (every trace versus sampling) and sovereign-zone deployment flexibility.

Splunk is often present as a SIEM and log analytics platform. The differentiation is that Splunk is excellent at log search but does not provide topology-aware correlation, automated remediation, or change risk scoring. Position Concert as complementary to Splunk (Concert ingests Splunk data as a signal source) rather than competitive.

11.7 Deal Sizing

Financial services sovereign operations deals typically range from USD 1M to USD 5M total contract value over 24–36 months, with the largest deals reaching USD 10M+ for global banking groups. Initial lands are often in the USD 500K–1M range, with expansion as coverage grows across business units and geographies.

> **WIIFM:** Financial services is the highest-value segment for sovereign operations. DORA creates a regulatory deadline that drives urgency. Deal sizes are large, renewal rates are high, and successful deployments generate powerful reference stories. Build relationships with the Head of Operational Resilience and the CTO; these are the two personas who control the budget. Every major bank in Europe is a DORA target; every major bank globally is a multi-cloud operations target. This is your largest addressable market.

---

12. Public Sector and Government

12.1 Regulatory and Policy Landscape

- **NIS2 Directive:** Applies to essential and important entities across EU member states, including government digital services, from October 2024. Requires cyber-security risk management, incident reporting, and supply chain security. Penalties up to EUR 10 million or 2% of global turnover.
- **Government Security Classifications (UK, NATO, Five Eyes):** Security clearance requirements, data classification, and operational controls for systems handling classified information.
- **FedRAMP / IL4-IL6 (US):** Federal Risk and Authorization Management Program and Impact Levels for cloud services used by US government agencies.
- **eIDAS 2.0 / EU Digital Identity:** Requirements for sovereign identity infrastructure that operational systems must support.

- **National Sovereignty Policies:** Many nations require that operational control of government digital infrastructure remains within national jurisdiction, staffed by nationally cleared personnel, and auditable by national authorities.

12.2 Customer Pain Points

National sovereignty requirements. Government agencies increasingly require that not just data, but the entire operational control plane—including AI inference, monitoring backends, and automation engines—resides within national jurisdiction, operated by nationally cleared staff, and auditable by national authorities. SaaS-based operations tools that process operational data outside the country's borders are often prohibited.

Legacy estate complexity. Government digital estates typically include a mix of modern cloud-native services, legacy on-premises systems (some decades old), and edge deployments. Operational tooling must span this entire range—not just the modern workloads.

Procurement and approval cycles. Government procurement is slower than commercial purchasing, with formal tender processes, security accreditation requirements, and multi-stage approval workflows. Sellers must plan for 6–18 month sales cycles and engage early with the procurement process.

Transparency and public accountability. Government operations are subject to freedom of information requests, parliamentary scrutiny, and public audit. Operational governance must be demonstrable not just to internal auditors but to external oversight bodies.

12.3 Solution Emphasis

- **OpenShift** as the sovereign platform, deployable in government-accredited data centres and air-gapped environments
- **Self-hosted Instana, Concert, and Orchestrate** running entirely within sovereign infrastructure (no data leaves the jurisdiction)
- **Concert** for NIS2-compliant incident detection, classification, and reporting
- **Orchestrate** with zone-scoped tool registries restricted to nationally approved tools and nationally cleared operators
- **AAP** for governed automation that produces audit trails suitable for public accountability

12.4 Qualification Questions

- "Do your security requirements mandate that all operational tooling—including AI inference—runs within national jurisdiction?"
- "What is the security classification of the workloads that require operational governance?"
- "Do you have a current or planned NIS2 compliance programme?"
- "What is your procurement process, and what accreditation does operational tooling require before deployment?"
- "How do you currently provide operational governance evidence to external audit bodies?"
- "Can your current operational tools function in an air-gapped environment?"

12.5 Deal Sizing

Government sovereign operations deals range from USD 300K for departmental deployments to USD 10M+ for national-scale platforms. Sales cycles are typically 12–24 months. Early engagement with the procurement process—including pre-qualification, security accreditation, and relationship building with the architecture authority—is essential.

> **WIIFM:** Government deals are large, long-cycle, and highly competitive. The key differentiator is IBM's ability to deploy the entire sovereign operations stack on-premises or in air-gapped environments—a capability that most SaaS-native competitors cannot match. Once deployed, government contracts have the longest renewal cycles and the highest switching costs in the portfolio. The investment in the sales cycle pays off over 5–10 year contract periods. Engage your IBM Government team early and leverage existing IBM relationships with government CTOs and CISOs.

---

13. Healthcare and Life Sciences

13.1 Regulatory and Policy Landscape

- **GDPR and national health data regulations (EU):** Patient data is classified as special-category data requiring enhanced protections, explicit consent, and strict access controls.
- **HIPAA (US):** Health Insurance Portability and Accountability Act requirements for protected health information, including operational access controls and audit trails.
- **Medical Device Regulation (EU MDR):** AI-driven clinical decision support systems may be classified as medical devices, requiring CE marking, post-market surveillance, and incident reporting.
- **NHS Data Security and Protection Toolkit (UK):** Specific requirements for organisations handling NHS patient data.
- **Clinical safety standards (DCB0129, DCB0160):** UK standards requiring clinical safety assessment of health IT systems that could affect patient care.

13.2 Customer Pain Points

Patient data sovereignty. Healthcare organisations handle the most sensitive personal data in any industry. Operational tooling that processes patient data—even operational telemetry that may contain patient identifiers in log messages—must satisfy the same data protection requirements as the clinical systems themselves. Zone-local telemetry retention with zero-copy integration is not a nice-to-have; it is a data protection requirement.

Clinical safety. Operational failures in healthcare can affect patient care. An EHR system outage during a clinical episode is not just a service availability issue; it is a patient safety issue. Operational priorities must be calibrated to clinical risk, not just technical severity.

Research data governance. Clinical research organisations handling trial data, genomic data, and real-world evidence face overlapping governance requirements from multiple regulators (FDA, EMA, MHRA) and ethics committees. Operational governance must demonstrate that research data environments are managed with the same rigour as production clinical systems.

Interoperability complexity. Healthcare estates integrate dozens of systems (EHRs, lab information systems, imaging systems, pharmacy systems) through standards such as HL7 FHIR and DICOM. Operational visibility into these integration flows is critical for maintaining data consistency and clinical workflow continuity.

13.3 Solution Emphasis

- **Instana** for real-time monitoring of clinical application chains, including HL7 FHIR interfaces and integration engines
- **Concert** for clinically-aware incident prioritisation (mapping operational severity to clinical risk)
- **Orchestrate** with healthcare-specific approval gates (e.g., requiring clinical system owner approval before any action on an EHR system)
- **watsonx.governance** for governance of AI systems used in clinical decision support, diagnostic imaging, and population health

13.4 Qualification Questions

- "How do you ensure that operational telemetry from clinical systems does not contain patient identifiers that cross data protection boundaries?"
- "Do you have a clinical safety assessment process for your operational tooling?"
- "How do you prioritise operational incidents that affect patient-facing clinical systems versus administrative systems?"
- "Are you deploying AI systems in clinical decision support, and how are those governed?"
- "How do you demonstrate to NHS Digital or your national health authority that your operational practices satisfy their security requirements?"

13.5 Deal Sizing

Healthcare sovereign operations deals range from USD 250K to USD 3M. The clinical safety dimension often requires engagement with clinical informatics and patient safety teams in addition to IT operations—plan for a broader stakeholder map and longer qualification cycles.

> **WIIFM:** Healthcare is a growing segment for sovereign operations, driven by the convergence of digital health, AI in clinical care, and tightening data protection requirements. The clinical safety angle differentiates this from a generic IT operations conversation and creates urgency that pure cost or efficiency arguments do not. Engage with the Chief Clinical Information Officer (CCIO) and the Chief Nursing Information Officer (CNIO) in addition to the CTO—they are the stakeholders who understand that operational failure equals patient risk.

---

14. Telecommunications

14.1 Regulatory and Policy Landscape

- **European Electronic Communications Code (EECC):** Security and incident reporting obligations for telecom operators.
- **NIS2:** Telecoms operators are classified as essential entities with enhanced obligations.
- **National regulatory authorities (Ofcom, BNetzA, ARCEP, etc.):** Country-specific requirements for service quality, emergency services continuity, and lawful intercept.
- **3GPP standards and GSMA guidelines:** Industry standards for network operations, security, and service management that increasingly address cloud-native network functions and AI-driven operations.

14.2 Customer Pain Points

Network-scale operational complexity. Telecoms operators manage operational estates of extraordinary complexity: millions of network elements, real-time service assurance for voice and data services, and operational processes that must account for physical infrastructure (towers, cables, data centres) alongside virtualised and cloud-native network functions.

Service assurance for critical services. Emergency services (999/112/911), lawful intercept, and universal service obligations impose operational requirements that have no commercial equivalent. Operational failures affecting these services trigger regulatory scrutiny and potential fines, regardless of the root cause.

Cloud-native network function (CNF) transition. Telecoms operators are migrating from proprietary, hardware-based network functions to cloud-native, containerised network functions running on Kubernetes. This transition creates a period of dual-stack operations—legacy and cloud-native running simultaneously—that multiplies operational complexity.

Autonomous network ambitions. The telecoms industry has set ambitious targets for autonomous network operations (TMForum Autonomous Networks initiative). IBM's sovereign operations platform maps directly to this ambition, providing the AI-driven correlation, recommendation, and automated execution capabilities that autonomous networks require, with the governance controls that regulators demand.

14.3 Solution Emphasis

- **Instana** for cloud-native network function monitoring (Kubernetes-native, real-time, full-fidelity)
- **Concert** for service-impact analysis that maps network faults to affected services and customers
- **Orchestrate** for network operations workflows with multi-stage approval for changes affecting critical services
- **Turbonomic** for capacity management of virtualised and cloud-native network functions
- **OpenShift** as the platform for cloud-native network functions and the IBM operations stack

14.4 Solution Architecture Pattern for Telecommunications

Service impact analysis. Concert's entity graph is configured with the telecoms service model: network functions (physical and virtual), transport links, service instances, and customer segments. When a network fault is detected—a fibre cut, a base station failure, a core network function degradation—Concert traverses the service dependency graph to determine which services are affected, which customer segments are impacted, and what the estimated customer impact is (number of affected subscribers, affected service types, estimated revenue impact). This service impact analysis, which traditionally takes 30+ minutes of manual correlation, is produced by Concert in under 3 minutes.

CNF monitoring on OpenShift. Cloud-native network functions running on OpenShift are monitored by Instana at every layer: the Kubernetes platform, the container runtime, the CNF application, and the network interfaces. Instana's automatic instrumentation discovers new CNFs as they are deployed and adds them to the topology without manual configuration. This is critical in telecoms environments where CNF lifecycle operations (upgrades, scaling, failover) are frequent and must be monitored in real time.

Network operations centre (NOC) integration. Concert's situation management is designed to replace the traditional NOC dashboard landscape. Instead of dozens of screens showing different network domains, Concert provides a unified situation view that shows the operational state of the entire network in terms of service impact rather than element status. NOC operators engage with situations (correlated, prioritised, business-impact-assessed) rather than with raw alarms.

14.5 Qualification Questions

- "How do you currently correlate network faults with service impact on end customers?"
- "What is your strategy for operational management of cloud-native network functions alongside legacy network elements?"
- "How do you ensure that operational changes do not affect emergency services continuity?"
- "Where are you on the TMForum Autonomous Networks maturity curve?"
- "How do you manage the operational complexity of running dual-stack (legacy + cloud-native) network infrastructure?"
- "What is your current alarm-to-incident correlation approach, and how effective is it during major network events?"
- "How do you plan to achieve the operational automation required by your autonomous network roadmap?"

14.6 Deal Sizing

Telecommunications sovereign operations deals range from USD 500K to USD 8M, with the largest deals in tier-one mobile operators. The operational complexity and scale of telecoms estates drive larger deployments and higher per-unit volumes. OpenShift platform deals often accompany the operations stack, adding USD 500K–2M to the total contract value.

> **WIIFM:** Telecoms operators are among the most technically sophisticated buyers in the market. They understand operational complexity at a level that most enterprises do not. The autonomous networks narrative aligns perfectly with the progressive autonomy model. Win a tier-one telecoms operator and you have a reference that resonates across every other industry. These are also multi-year platform deals with significant expansion potential as the operator's CNF migration progresses.

---

15. Energy and Utilities

15.1 Regulatory and Policy Landscape

- **NIS2:** Energy is classified as an essential sector with enhanced obligations for cyber-security risk management and incident reporting.
- **NERC CIP (US/Canada):** North American Electric Reliability Corporation Critical Infrastructure Protection standards for the bulk electric system.

- **IEC 62443:** International standard for industrial automation and control system security, increasingly applied to operational technology in energy and utilities.
- **National critical infrastructure regulations:** Country-specific requirements for the protection and resilience of energy infrastructure.

15.2 Customer Pain Points

IT/OT convergence. Energy and utility companies are converging their information technology (IT) and operational technology (OT) environments. Smart grids, connected metering, and industrial IoT create operational estates that span traditional IT infrastructure and industrial control systems. Operational tooling must bridge this gap without introducing security risks to the OT environment.

Critical national infrastructure obligations. Energy infrastructure is classified as critical national infrastructure in most jurisdictions, subjecting operators to the highest tier of regulatory requirements for operational resilience, incident reporting, and supply chain security.

Geographic distribution. Energy assets are physically distributed across wide geographic areas—power plants, substations, wind farms, oil platforms—creating operational challenges around connectivity, latency, and edge computing that centralised SaaS-based operations tools cannot address.

Safety and environmental risk. Operational failures in energy infrastructure can create physical safety hazards (equipment damage, electrical faults, gas leaks) and environmental damage (oil spills, emissions events). The consequence of operational failure extends beyond financial loss to public safety and environmental liability.

15.3 Solution Emphasis

- **OpenShift** at the edge for distributed operational management of geographically dispersed assets
- **Instana** for monitoring of both IT and containerised OT workloads
- **Concert** for cross-domain correlation between IT faults and OT operational impacts
- **Orchestrate** with safety-critical approval gates for any action that could affect physical infrastructure
- **AAP** for governed automation of operational procedures across distributed sites

15.4 Qualification Questions

- "How do you manage the operational boundary between your IT and OT environments?"
- "Can your current operational tooling span both traditional IT infrastructure and industrial control systems?"
- "How do you ensure operational visibility into assets at distributed geographic locations (substations, wind farms, remote facilities)?"
- "What are your regulatory reporting obligations for operational incidents affecting critical infrastructure?"
- "How do you manage the physical safety implications of operational actions on energy infrastructure?"

15.5 Deal Sizing

Energy and utilities sovereign operations deals range from USD 300K to USD 5M. The IT/OT convergence and geographic distribution dimensions often drive multi-phase deployments that expand over 2–3 years. Edge deployment requirements favour OpenShift-based solutions, adding platform revenue to the deal.

> **WIIFM:** Energy and utilities is a growing segment driven by IT/OT convergence, smart grid modernisation, and NIS2 compliance. The physical safety dimension elevates the conversation beyond IT operations into enterprise risk management, which brings C-suite attention and budget. IBM's ability to deploy at the edge—on OpenShift, with disconnected or intermittently connected operations—is a significant differentiator against SaaS-native competitors.

---

16. Cross-Industry Patterns

Across all five industry verticals, five structural patterns recur. Understanding these patterns helps you position the IBM portfolio consistently regardless of industry:

1. **Observability must precede automation.** In every case study and every successful deployment, organisations that attempted to automate operations without first establishing comprehensive observability failed or were forced to retreat. Instana is always Phase 1, regardless of the play or the industry. You cannot automate what you cannot see.

2. **Zone design reflects regulatory geography, not technical architecture.** Sovereign zones are not data centres or cloud regions; they are regulatory jurisdictions. A zone boundary corresponds to a supervisory authority's reach: the ECB's supervision zone, the FCA's supervision zone, the MAS supervision zone. Technical architecture adapts to this regulatory geography, not the other way around.

3. **Policy-as-code is the enforcement mechanism.** In every regulated industry, governance policies must be enforceable automatically, not just documented. Policies expressed as code—evaluated at execution time by the governance plane—provide the continuous enforcement that regulators now expect. Manual policy enforcement (checking a spreadsheet before making a change) does not scale and cannot be audited continuously.

4. **Progressive autonomy is the only responsible path to automation.** No regulated organisation should leap from manual operations to autonomous self-healing. The progressive autonomy model—manual, advisory, assisted, conditionally automated, supervised autonomous—provides a governed path that builds evidence and confidence at each level before advancing to the next. The Sovereign Operations Maturity Model gives both the customer and the seller a framework for this progression.

5. **The audit trail is not a feature; it is the product.** In regulated industries, the ability to demonstrate what was done, by whom, when, under what authority, and with what outcome is not a nice-to-have feature of the operations platform—it is the primary reason for the investment. Every component of the IBM stack contributes to the audit trail: Instana records what was observed, Concert records what was correlated and recommended, Orchestrate records what was approved and executed, AAP records what was changed, and watsonx.governance records how the AI systems behaved. Together, they produce the continuous compliance evidence that regulators demand.

   WIIFM: These five patterns give you a consistent narrative across all industries. Memorise them. They work in every first meeting, regardless of whether you are talking to a bank, a hospital, a government agency, or a telecoms operator. They position you as someone who understands the discipline, not just the products.

Part V — Execution and Engagement

17. Competitive Positioning Summary

17.1 Versus Hyperscaler-Native Tools (AWS CloudWatch / Azure Monitor / GCP Operations)

Their strength: Deep, low-cost monitoring within their own platform. Native integration with their services. No additional procurement.

Their limitation: Architecturally blind to other clouds. An AWS CloudWatch dashboard cannot show an Azure service dependency or an on-premises database bottleneck. In a multi-cloud estate, hyperscaler-native tools create siloed views that multiply investigation time and prevent cross-cloud correlation.

Your message: "We do not replace CloudWatch or Azure Monitor. We complement them. IBM provides the cross-cloud control plane that correlates signals from all your clouds—including the hyperscalers' own tools—into a single operational picture. No hyperscaler will ever build this because it would require them to treat their competitors' platforms as equal citizens."

Evidence points: Cross-cloud situation correlation (47 alerts from 3 clouds = 1 Concert situation). Zero-copy integration preserving data residency. Zone-scoped governance that hyperscaler tools cannot enforce across cloud boundaries.

17.2 Versus ServiceNow IT Operations Management

Their strength: Ubiquitous ITSM platform. Established workflow engine. Strong brand in IT operations management. Already deployed in most enterprises.

Their limitation: ServiceNow ITOM relies on a CMDB that is typically stale, incomplete, and manually maintained. Its AIOps capabilities are additive (bolted on) rather than native. It does not provide the depth of observability that Instana offers, the application-aware resource optimisation that Turbonomic provides, or the agentic conversational operations that Orchestrate enables.

Your message: "We integrate with ServiceNow—bidirectionally. Concert creates and updates ServiceNow incidents automatically, and ServiceNow change approvals flow back to Concert. We are not asking you to replace ServiceNow as your system of record. We are providing the intelligence and automation layer that makes ServiceNow more accurate and your operations team more effective."

Evidence points: Bidirectional ITSM synchronisation. Live topology versus stale CMDB. Alert-to-situation compression ratios. Conversational workflow execution versus form-based workflows.

17.3 Versus Datadog

Their strength: Developer-friendly UX. Strong APM and log management. Rapid market share growth. Cloud-native architecture.

Their limitation: SaaS-only deployment model. All telemetry must leave the customer's environment and transit to Datadog's infrastructure. For organisations with sovereign-zone requirements, data-residency obligations, or air-gapped environments, this is a disqualifier. Sampling-based tracing loses fidelity for the rare transactions that matter most in regulated environments.

Your message: "Datadog is a strong monitoring tool for cloud-native workloads in environments without data-residency constraints. For organisations that must keep operational telemetry within their jurisdiction, that need full-fidelity tracing of every transaction, and that require an AI-driven operations layer that can execute actions—not just alert—IBM provides capabilities that Datadog's architecture cannot deliver."

Evidence points: Self-hosted and air-gapped deployment models. Every-trace capture versus sampling. Situation management and automated remediation versus alert-and-dashboard.

17.4 Versus Dynatrace

Their strength: Strong APM with automatic instrumentation. Good Kubernetes monitoring. Established enterprise customer base.

Their limitation: Primarily SaaS-delivered. Limited sovereign-zone deployment flexibility. Does not provide the breadth of the IBM portfolio—no equivalent to Turbonomic's resource optimisation, Orchestrate's conversational operations, or Concert's change risk scoring. Davis AI is correlation-focused but does not extend to agentic execution.

Your message: "Dynatrace provides good APM, and we respect it. IBM's differentiation is the breadth and depth of the platform: from observability through AIOps correlation, conversational operations, governed automation, resource optimisation, and AI governance—an integrated stack that Dynatrace does not offer. For sovereign operations specifically, IBM's deployment flexibility and zone-aware architecture are significant differentiators."

Evidence points: Platform breadth comparison (Instana + Concert + Orchestrate + Turbonomic + watsonx.governance + AAP versus Dynatrace standalone). Sovereign-zone deployment flexibility. Agentic execution capability.

17.5 Versus Splunk

Their strength: Strong log management and SIEM capabilities. Large existing customer base. Broad integration ecosystem.

Their limitation: Splunk is fundamentally a log analytics platform, not an operations platform. It excels at search and analysis but does not provide automatic topology discovery, application-aware resource optimisation, or agentic workflow execution. Splunk's acquisition by Cisco may create uncertainty about future direction and integration.

Your message: "Splunk is excellent at log analytics. IBM Concert is designed for a different problem: correlating signals from across the operational estate—not just logs, but metrics, traces, topology changes, and business events—into actionable situations with recommended remediation. If the customer needs log analytics, Splunk is fine. If they need operational intelligence and governed automation, IBM is the answer."

---

18. Objection Handling

The following objections are the ones sellers encounter most frequently. Each is addressed with a structured response that acknowledges the concern, provides evidence, and redirects the conversation.

Objection 1: "We are already invested in [Datadog/Dynatrace/ServiceNow]. Why would we rip and replace?"

Response: "You would not. IBM does not require rip and replace. Instana and Concert complement existing monitoring tools by providing the cross-cloud correlation and AIOps intelligence layer that sits above them. Concert ingests signals from Datadog, Dynatrace, CloudWatch, Azure Monitor, and ServiceNow via native connectors and OpenTelemetry. ServiceNow remains your system of record; Concert makes it more accurate with bidirectional synchronisation. The question is not 'replace your monitoring tools' but 'who provides the cross-cloud intelligence layer that your existing tools cannot?' "

Objection 2: "We can build this ourselves with open-source tools."

Response: "You can build individual components—Prometheus for metrics, Jaeger for tracing, Grafana for dashboards. What you cannot easily build is the correlation engine that turns thousands of alerts into actionable situations, the topology-aware causal inference that identifies root causes, the conversational interface that translates recommendations into governed actions, or the change risk scoring that integrates into your CI/CD pipelines. The build-versus-buy calculation should include the engineering cost of building and maintaining these capabilities, which typically requires 5–10 dedicated engineers. At USD 200K per engineer fully loaded, that is USD 1–2M per year in perpetuity—more than the IBM platform investment, with greater risk and slower time to value."

Objection 3: "IBM is trying to create lock-in with a proprietary stack."

Response: "The architecture is designed around open standards specifically to prevent this. Instana supports OpenTelemetry bidirectionally. Concert ingests from any monitoring source. Orchestrate's tool registry is API-driven and can call any tool with an API. The entire stack runs on Kubernetes (OpenShift or any CNCF-conformant distribution). Each component can be substituted independently. We document exit paths as part of the architecture. Compare this to a hyperscaler-native operations stack where everything is proprietary to that platform—that is lock-in. IBM's approach is strategic optionality."

Objection 4: "We are not ready for AI in operations. We need to get the basics right first."

Response: "We agree completely. That is why the deployment is phased. Phase 1 is observability—getting a single view of your estate with Instana. That is not AI; that is instrumentation and topology. Phase 2 adds Concert for correlation and triage—using AI to reduce alert noise, not to take autonomous action. Phase 3, which may be 12–18 months away, introduces workflow automation with human approval gates at every step. The progressive autonomy model means you adopt AI at the pace your organisation is ready for. No action is ever taken without your explicit configuration and approval."

Objection 5: "The pricing is too high for our budget."

Response: "Let us look at the value rather than the price. If your current cost-per-incident is USD 150,000 and Concert reduces major incidents by 40%, that is USD 600,000 in avoided cost against a platform investment of USD 400,000. If Turbonomic identifies 25% cloud waste in a USD 10M estate, that is USD 2.5M in savings against a USD 300K investment. The platform is designed to be self-funding within 12 months. Let us run a 30-day proof of value with Turbonomic to generate the data for your specific business case."

Objection 6: "We had a bad experience with a previous AIOps tool. They all overpromise."

Response: "That is a fair concern, and we hear it frequently. The most common reason AIOps deployments fail is that they try to correlate alerts without an accurate topology model—they are doing pattern matching on noise. Concert's differentiation is the live entity graph: it builds and maintains a real-time model of your application dependencies, so correlation is topology-aware rather than purely statistical. We are happy to run a time-boxed proof of concept with measurable success criteria defined in advance—alert compression ratio, mean time to root cause, false positive rate—so you can evaluate the results before committing."

Objection 7: "Our hyperscaler already provides these capabilities."

Response: "Your hyperscaler provides excellent capabilities within their own platform. The question is: what about the other 40–60% of your estate that runs on a different cloud or on-premises? When an incident spans cloud boundaries—and in a multi-cloud estate, many do—your hyperscaler's tools see only their portion of the story. IBM provides the cross-cloud correlation layer. We complement your hyperscaler investment; we do not compete with it."

Objection 8: "We need to see this work in an environment like ours before we commit."

Response: "Absolutely. We offer several proof-of-value approaches: a 30-day Turbonomic waste analysis (typically free or low-cost), a Concert proof of concept with defined success criteria, or an Instana trial deployment against a representative subset of your estate. Each is time-boxed, low-risk, and designed to generate the data you need to make a decision. We can also arrange reference calls with organisations in your industry who have deployed the platform."

Objection 9: "We are concerned about the operational overhead of managing another platform."

Response: "The platform is designed to reduce operational overhead, not add to it. Instana auto-discovers and auto-instruments—no manual agent configuration. Concert correlates alerts that your team currently investigates manually—reducing their workload, not increasing it. Orchestrate automates multi-step workflows that operators currently perform across multiple tools. The net effect is fewer tools to manage, not more. And the entire stack runs on OpenShift with Operator-managed lifecycle, so upgrades and maintenance are handled consistently."

Objection 10: "Our CISO is concerned about the security of a cross-cloud control plane."

Response: "That is the right question, and we welcome it. The architecture addresses the 'who watches the watchmen' concern directly. The control plane uses distributed trust: zone-scoped credentials with just-in-time elevation, so no single credential provides access across all zones. Zone-local enforcement means that even if the central control plane is compromised, it cannot execute actions in a zone without passing through that zone's local policy enforcement. Every action requires short-lived, scoped credentials from the identity fabric. The blast radius of any control plane breach is bounded by design. We are happy to conduct a security architecture review with your CISO and security architecture team."

---

19. Deal Structure and Commercial Guidance

19.1 Deal Sizing Ranges

The following ranges are indicative and vary by customer size, estate complexity, and geographic scope:

Deal Type	Typical ACV Range	Typical TCV (3-year)	Entry Point
Observability Only (Instana)	USD 150K–500K	USD 450K–1.5M	30-day trial
Cost Optimisation (Turbonomic)	USD 200K–600K	USD 600K–1.8M	30-day PoV
AIOps (Instana + Concert)	USD 400K–1.5M	USD 1.2M–4.5M	Observability PoC
Sovereign Operations Platform	USD 800K–3M	USD 2.4M–9M	Maturity assessment
Full Autonomous Operations	USD 1.5M–5M	USD 4.5M–15M	Executive workshop

19.2 Commercial Models

Subscription licensing. Annual subscription based on monitored entity count (Instana), managed resources (Turbonomic), or connected services (Concert). This is the standard commercial model and the one most customers prefer for predictability and flexibility.

Enterprise licence agreement (ELA). For large customers deploying across the full estate, an ELA provides a fixed annual fee for unlimited deployment within agreed scope. ELAs simplify procurement, reduce per-unit cost, and create a long-term relationship. Typical ELA threshold is USD 1M+ ACV.

Passport Advantage. IBM's standard volume licensing programme for software. Suitable for customers who prefer term-based licensing with support included.

Managed service. For customers who want the capabilities but not the operational burden of managing the platform, IBM Technology Expert Labs or a Business Partner can provide managed services. This model typically adds 30–50% to the software cost but eliminates the customer's platform management overhead.

19.3 Pricing Principles (Not Specific Prices)

- **Land and expand.** Start with a focused deployment (one product, one environment) and expand as value is demonstrated. Do not try to sell the full stack on day one unless the customer's maturity and urgency justify it.
- **Self-funding positioning.** Position the investment as self-funding wherever possible: Turbonomic savings offset cost; incident reduction offsets Concert investment; automation efficiency offsets Orchestrate and AAP investment. Build the business case with the customer's own data.
- **Multi-year commitment discount.** Three-year commitments typically receive a 15–25% discount over annual pricing, which improves the customer's TCO and your deal economics.
- **Bundle pricing.** When selling multiple products (Instana + Concert + Orchestrate), bundle pricing is more attractive than individual product pricing and encourages platform adoption over point-product purchasing.

  WIIFM: The commercial model flexibility is your deal-structuring advantage. You can enter with a small, low-risk engagement (Turbonomic PoV, Instana trial) and expand into a platform deal as value is demonstrated. Multi-year commitments improve your quota attainment and the customer's economics. ELAs for large customers simplify procurement for both sides and lock in multi-year revenue. Use bundle pricing to pull multiple products into the deal and increase ACV.

20. Engagement Model

20.1 Phase 0: Discovery and Qualification (Weeks 1–4)

Objective: Determine whether the customer has the pain, the budget, and the organisational readiness for a sovereign operations investment.

Activities:

- Initial discovery meeting with IT leadership (CTO, VP Ops, Head of SRE)
- Administer the sovereign operations pain assessment (structured questionnaire covering the four planes)
- Conduct a lightweight maturity assessment using the Sovereign Operations Maturity Model (self-assessment version)
- Identify buying signals from the qualification matrix
- Map the buying committee and decision-making process
- Qualify budget: is there allocated budget, or does a business case need to be built?

Deliverables:

- Completed pain assessment and maturity self-assessment
- Buying committee map with roles, influence, and disposition
- Qualification decision: pursue (with play recommendation) or nurture
- If pursue: draft engagement plan for Phase 1

Milestones:

- Discovery meeting completed (Week 1)
- Pain assessment completed (Week 2)
- Buying committee mapped (Week 3)
- Qualification decision and engagement plan (Week 4)

Key discovery questions for Phase 0:

- "What keeps you up at night about your operations?"
- "If you could solve one operational problem this year, what would it be?"
- "Who else in the organisation cares about this problem? Who controls the budget?"
- "What have you tried before, and what was the result?"
- "What is the consequence if you do nothing for the next 12 months?"
- "Is there a regulatory deadline or business event driving urgency?"

20.2 Phase 1: Proof of Value (Weeks 5–12)

Objective: Demonstrate measurable value in the customer's own environment with a focused, time-boxed deployment.

Activities:

- Deploy the entry-point product(s) against a representative subset of the customer's estate:
  - **Turbonomic PoV:** 30-day waste analysis, typically free or low-cost. Generates quantified savings report.
  - **Instana trial:** 30-day full-stack observability deployment. Generates topology map, health baselines, and incident correlation data.
  - **Concert PoC:** 60-day AIOps proof of concept with defined success criteria (alert compression ratio, MTTR improvement, false positive rate).
- Measure and report against pre-agreed success criteria
- Build the business case with customer-specific data
- Present findings to the buying committee

Deliverables:

- PoV/PoC results report with measured outcomes versus success criteria
- Customer-specific business case (cost avoidance, efficiency gain, risk reduction)
- Recommended deployment plan for Phase 2
- Commercial proposal

Milestones:

- PoV/PoC deployment completed (Week 6)
- Mid-point review with customer (Week 8)
- Results analysis and business case preparation (Week 10)
- Executive presentation and commercial proposal (Week 12)

20.3 Phase 2: Foundation Deployment (Months 4–9)

Objective: Deploy the core sovereign operations platform across the customer's estate with production-grade configuration.

Activities:

- Full deployment of selected products across agreed environments
- Integration with customer's existing tools (ITSM, CI/CD, identity, SIEM)
- Configuration of zone-aware policies and governance controls
- Operator training and enablement
- Establishment of operational KPIs and measurement baseline

Deliverables:

- Production deployment across agreed scope
- Integration documentation and operational runbooks
- Operator training completion
- KPI baseline report
- Expansion roadmap for Phase 3

Milestones:

- Architecture and design complete (Month 4)
- Deployment and integration complete (Month 6)
- Operator training complete (Month 7)
- KPI baseline established (Month 8)
- Phase 3 planning (Month 9)

20.4 Phase 3: Expansion and Maturation (Months 10–24)

Objective: Expand coverage, increase automation, and advance the customer's sovereign operations maturity.

Activities:

- Expand coverage to additional environments, business units, and geographies
- Implement progressive automation for approved remediation categories
- Deploy additional products (e.g., add Orchestrate if Phase 2 was Instana + Concert)
- Conduct quarterly maturity assessments against the Sovereign Operations Maturity Model
- Establish continuous improvement programme with quarterly reviews

Deliverables:

- Expanded deployment across full estate
- Progressive automation implementation with measured outcomes
- Quarterly maturity assessment reports showing progression
- Continuous improvement roadmap
- Renewal and expansion commercial proposal

Milestones:

- Expanded deployment complete (Month 12)
- First automated remediation categories in production (Month 14)
- Quarterly maturity assessment (Months 12, 15, 18, 21, 24)
- Renewal conversation (Month 18)
- Expansion proposal (Month 20)

20.5 Stakeholder Management Across Phases

Different personas are critical at different phases. Map your engagement strategy accordingly:

Phase	Primary Stakeholder	Secondary Stakeholders	Key Message
Phase 0	CTO / VP Ops	Head of SRE, Head of Architecture	"Let us assess where you are and where the gaps are"
Phase 1	Head of SRE / Platform Lead	CTO, FinOps Lead	"Here is measurable proof in your own environment"
Phase 2	CTO / VP Infrastructure	CISO, CRO, Head of Procurement	"Here is the platform that closes the gaps we identified"
Phase 3	CTO / CIO	CFO, Board Risk Committee	"Here is the ongoing value and the expansion path"

Critical success factors across all phases:

- **Executive sponsorship.** Every successful sovereign operations deployment has a named executive sponsor who owns the outcome. Without one, the programme stalls at the first organisational obstacle. Identify the sponsor in Phase 0; engage them at every phase gate.
- **Architecture authority engagement.** The customer's architecture team must be involved from Phase 0. If they are excluded, they will become blockers in Phase 2 when the deployment requires architectural decisions about zone design, integration patterns, and data flows.
- **Operations team buy-in.** The people who will use the platform daily must see it as a tool that makes their work better, not a management surveillance system. Involve the operations team in PoV/PoC activities. Their enthusiastic feedback is the most powerful internal advocacy for the investment.
- **Quick wins visibility.** Ensure that early wins (first situation correlated, first alert storm compressed, first automated remediation executed) are visible to the executive sponsor and the buying committee. These wins build momentum and justify continued investment.

20.6 Risk Mitigation in the Engagement

Every engagement carries risks. Anticipate and mitigate these common ones:

Risk	Mitigation
PoV/PoC fails to demonstrate value	Define success criteria in advance with measurable, achievable targets. Choose a representative subset of the estate, not the most complex corner case.
Scope creep in Phase 2	Fix the scope at the Phase 1/Phase 2 gate. Document what is in scope and what is deferred to Phase 3. Use the maturity assessment to justify phasing.
Organisational resistance to automation	Start with advisory mode (Concert recommends, humans decide). Build trust incrementally. Do not push for automated execution until operators are confident.
Key stakeholder leaves mid-programme	Build relationships with multiple stakeholders. Document the business case and phase outcomes so they survive personnel changes.

Risk	Mitigation
Integration complexity exceeds estimate	Conduct an integration assessment in Phase 0. Identify all systems that must integrate (ITSM, CI/CD, identity, SIEM) and assess readiness. Engage IBM Expert Labs for complex integrations.
Budget approval delayed	Structure the engagement so each phase is independently fundable. Phase 1 can often be funded from the operations team's existing budget. Phases 2 and 3 require business-case justification, which Phase 1 generates.

> **WIIFM:** The four-phase engagement model gives you a structured path from first meeting to multi-year platform deal. Phase 0 costs you nothing but time. Phase 1 costs the customer little or nothing but generates the data that sells Phases 2 and 3. Each phase is independently valuable and independently closable, but the full engagement generates the highest ACV and the strongest customer relationship. Use the phase model to manage customer expectations and your own pipeline forecasting.

---

21. Maturity Assessment as a Sales Tool

21.1 The Sovereign Operations Maturity Model (SOMM)

The maturity model provides a structured assessment framework that serves dual purposes: it helps the customer understand their current state and target state, and it gives you a gap analysis that maps directly to the IBM portfolio.

Five maturity levels:

Level	Name	Description	IBM Portfolio Mapping
Level 1	Ad-hoc and Reactive	No consistent operational practices. Firefighting mode. Multiple disconnected tools. No automation.	Instana for observability baseline
Level 2	Foundational	Basic monitoring in place. Some standard processes. Limited automation. ITSM for incident tracking.	Instana + Concert for correlation
Level 3	Proactive	Cross-cloud observability. AIOps correlation. Some automated remediation. Policy-as-code.	Full stack: Instana + Concert + Orchestrate + AAP
Level 4	Optimised	Comprehensive automation. Progressive autonomy. Continuous compliance. Measured outcomes.	Full stack + watsonx.governance + Turbonomic
Level 5	Autonomous	Self-healing for approved categories. AI-driven optimisation. Continuous improvement.	Full stack at maturity with expanded automation

Eight assessment dimensions:

1. Infrastructure codification (IaC maturity)
2. Observability depth (metrics, traces, logs, topology)
3. Automation coverage (percentage of operations automated)

4. Sovereignty enforcement (zone policies, data residency, access control)
5. Agent adoption (AI-assisted and automated operations)
6. Governance maturity (audit trails, compliance evidence, policy-as-code)
7. Cultural readiness (team structure, skills, collaboration)
8. Knowledge management (runbooks, documentation, learning from incidents)

21.2 Using the Assessment in the Sales Process

How to conduct the assessment:

1. Use the SOMM self-assessment questionnaire (available in the Deal Acceleration Kit) during Phase 0 discovery
2. Have the customer rate themselves on each dimension (1–5 scale) with evidence
3. Map the results to a radar chart showing current state across all eight dimensions
4. Identify the dimensions with the largest gaps between current and target state
5. Map each gap to specific IBM capabilities
6. Use the gap analysis to structure the engagement plan and commercial proposal

Why it works: The maturity assessment positions you as a trusted adviser, not a product salesperson. The customer self-identifies their gaps; you provide the capabilities to close them. The assessment also creates a natural quarterly review cadence (re-assess, measure progress, plan next steps) that sustains the relationship and drives expansion.

21.3 Common Maturity Patterns and What They Mean for Sellers

Through hundreds of assessments, several common maturity patterns have emerged. Recognising these patterns helps you select the right play and set expectations:

Pattern 1: Strong observability, weak automation. The customer has invested in monitoring (Levels 3–4 on observability depth) but has low automation coverage (Level 1–2). They can see problems quickly but respond to them slowly and manually. This customer is ready for the Autonomous Operations Play (Play 4), starting with Orchestrate and AAP. The observability foundation is already in place; the gap is in the action layer.

Pattern 2: Strong automation, weak governance. The customer has automated many operational tasks but lacks the governance, audit trail, and policy-as-code enforcement that regulated environments require. This is common in organisations that built automation organically without regulatory pressure and are now facing DORA or NIS2 compliance. This customer needs Concert for governance and audit trail, watsonx.governance for AI governance, and a policy-as-code framework. The Regulatory Compliance Play (Play 1) is the right entry.

Pattern 3: Uniformly low maturity. The customer is at Level 1 or 2 across all dimensions. They need the full journey but cannot absorb a full platform deployment at once. Start with the AIOps Consolidation Play (Play 2) focused on Instana + Concert. Build the foundation first; expand from there.

Pattern 4: High maturity in one cloud, low in others. The customer has invested heavily in one cloud's native tooling (typically AWS) and has strong operational practices there, but recently expanded to a second cloud (typically Azure) where operational maturity is much lower. The cross-cloud gap creates the Multi-Cloud Control Plane Play (Play 5) opportunity.

Pattern 5: Strong technical maturity, weak cultural readiness. The customer has the tools and technology but the organisation has not adapted its processes, team structure, or culture to take advantage of them. This is the hardest pattern to sell into because the problem is organisational, not technological. Consider engaging IBM Consulting to address the organisational change dimension alongside the technology deployment.

> **WIIFM:** The maturity assessment is your most powerful qualification and positioning tool. It takes 60–90 minutes to conduct, costs nothing, and produces a gap analysis that maps directly to the IBM portfolio. Customers who complete the assessment close at significantly higher rates than those who do not, because they have a data-driven understanding of their own gaps. Use it in every Phase 0 engagement. The radar chart is also an excellent visual for executive presentations.

---

22. Case Study Evidence

22.1 European Tier-1 Bank — DORA Compliance and AIOps Transformation

Context: A European tier-1 bank operating across 14 EU member states, with workloads on AWS, Azure, and on-premises data centres. 2,400 applications, 180,000 infrastructure components, 12 monitoring tools.

Challenge: DORA compliance deadline with no ability to demonstrate cross-cloud operational governance. Major incidents required 90+ minutes to triage due to alert fragmentation across tools. Change failure rate of 18%. Regulatory examination had identified operational governance as a material weakness.

Solution deployed: Instana for cross-cloud observability; Concert for AIOps correlation and situation management; Orchestrate for governed remediation workflows; ServiceNow bidirectional integration.

Outcomes:

- Alert-to-situation compression ratio: 23:1 (average), reducing operator cognitive load by over 90%
- MTTR reduced from 94 minutes to 37 minutes (61% improvement)
- Change failure rate reduced from 18% to 7% through change risk scoring in CI/CD pipelines
- Regulatory examination cleared with commendation for operational governance maturity
- False positive rate: 8% (below the 15% threshold that erodes operator trust)
- Automation coverage: 34% of routine remediation actions automated within 12 months
- Estimated annual cost avoidance: EUR 4.2M (incident cost reduction + toil reduction + regulatory fine avoidance)

Deal value: EUR 2.8M TCV over 36 months.

22.2 National Health Service Trust — Clinical Operations and Patient Data Sovereignty

Context: A large NHS Trust operating electronic health records, clinical decision support, and patient administration across 6 hospital sites and 40 community clinics. Workloads on NHS Cloud (Azure-based) and on-premises data centres.

Challenge: Patient data sovereignty requirements prevented the use of SaaS-based monitoring tools that process data outside UK jurisdiction. Clinical system outages affected patient care but were detected by clinical staff before the operations team. No correlation between IT operational events and clinical impact.

Solution deployed: Self-hosted Instana on OpenShift for zone-local observability; Concert for clinically-aware incident prioritisation; Orchestrate for governed remediation with clinical safety approval gates.

Outcomes:

- Mean time to detect clinical system degradation reduced from 23 minutes (detected by clinical staff) to 2 minutes (detected by Instana)
- Clinical incident response time reduced by 78%
- Zero patient data sovereignty violations (all operational telemetry remains within UK jurisdiction)
- Clinical safety incidents related to IT operational failures reduced by 67%
- Operations team able to prioritise incidents based on clinical impact rather than technical severity alone

Deal value: GBP 450K TCV over 24 months.

22.3 Tier-1 Mobile Operator — Autonomous Network Operations

Context: A tier-1 European mobile operator with 35 million subscribers, migrating from legacy network functions to cloud-native network functions on OpenShift. 2 million network elements, real-time service assurance requirements.

Challenge: Dual-stack operations (legacy + cloud-native) created operational complexity that exceeded the team's capacity. Alert volume during network incidents exceeded 10,000 per hour. Service impact assessment for network faults required manual correlation that took 30+ minutes.

Solution deployed: Instana for cloud-native network function monitoring; Concert for service impact analysis and network-aware correlation; Turbonomic for capacity management of virtualised network functions; OpenShift as the CNF platform.

Outcomes:

- Alert-to-situation compression ratio: 47:1 during major network events
- Service impact assessment time reduced from 35 minutes to 3 minutes
- Network incident MTTR reduced by 54%
- Cloud-native network function resource utilisation improved by 28% through Turbonomic optimisation
- Progression from TMForum Autonomous Networks Level 1 to Level 3 within 18 months

Deal value: EUR 4.1M TCV over 36 months (including OpenShift platform).

22.4 Government Digital Services — Sovereign Operations for National Infrastructure

Context: A national government digital services agency responsible for citizen-facing digital services (tax, benefits, identity) running across government-accredited data centres with no public cloud. Air-gapped classified environments alongside standard government networks.

Challenge: NIS2 compliance requirements with national sovereignty mandate: all operational tooling must run within national jurisdiction, operated by nationally cleared staff. No SaaS-based tools permitted for classified workloads. Fragmented monitoring with no cross-service correlation.

Solution deployed: Air-gapped OpenShift deployment with self-hosted Instana, Concert, and Orchestrate. Zone separation between classified and standard environments with no cross-zone data movement.

Outcomes:

- First unified operational view across all government digital services
- NIS2 compliance achieved with automated evidence generation
- Incident correlation reduced investigation time by 65%
- Automated compliance reporting saving 2,400 staff-hours per year
- Classified environment operational tooling operating entirely within air-gapped boundary

Deal value: EUR 3.2M TCV over 48 months.

22.5 Insurance Group — Multi-Cloud Cost Optimisation and Operational Efficiency

Context: A European insurance group operating across AWS, Azure, and on-premises, with USD 22M annual cloud spend. 800 applications, 3 operations teams (one per cloud), 8 monitoring tools.

Challenge: Cloud spend growing 35% year-on-year with no corresponding business growth. Each cloud team managed its own monitoring, runbooks, and incident processes with no standardisation. Major incidents spanning cloud boundaries required assembling all three teams for manual coordination.

Solution deployed: Turbonomic for cross-cloud cost optimisation; Instana for unified observability; Concert for cross-cloud incident correlation.

Outcomes:

- Cloud spend reduced by 31% (USD 6.8M annual saving) through Turbonomic optimisation
- Three operations teams consolidated into one cross-cloud team (enabled by unified tooling)
- Monitoring tool count reduced from 8 to 3 (Instana + retained cloud-native tools)
- Cross-cloud incident MTTR reduced from 72 minutes to 28 minutes
- Turbonomic ROI: 11x in the first year (USD 6.8M savings against USD 620K investment)

Deal value: USD 1.4M TCV over 36 months.

> **WIIFM:** Case studies close deals. When a prospect in financial services hears that a comparable bank achieved 61% MTTR reduction and cleared its regulatory examination, the conversation shifts from "will this work?" to "when can we start?" Learn these case studies and use them proactively. Match the case study to the prospect's industry, pain points, and deal size. Offer reference calls where appropriate—a peer conversation is more persuasive than any sales presentation.

23. Deal Acceleration Kit

The following resources are available to support your sales motion:

Resource	Purpose	Where to Find It
Sovereign Operations Maturity Assessment	Phase 0 qualification and gap analysis	Seismic / IBM Sales Kit
Customer Pain Assessment Questionnaire	Structured discovery for initial meetings	Seismic / IBM Sales Kit
Four-Plane Whiteboard Template	First-meeting positioning framework	Seismic / IBM Sales Kit
Value Calculator	Customer-specific ROI modelling	IBM Technology Expert Labs
Turbonomic Proof of Value Offer	30-day free waste analysis	Turbonomic Sales Team
Concert Proof of Concept Guide	60-day PoC with defined success criteria	Concert Sales Team
Industry-Specific Battle Cards	Competitive positioning by industry	Seismic / IBM Sales Kit
Customer Reference Database	Peer reference matching by industry and use case	IBM Reference Programme
Sovereign Cloud Operations Book	Full technical depth for architect engagement	Available via IBM internal distribution
Executive Briefing Deck	C-suite positioning of sovereign operations	Seismic / IBM Sales Kit
DORA/NIS2 Compliance Mapping	Regulation-to-capability mapping	IBM Expert Labs
Deal Structure Templates	Commercial proposal templates by deal type	IBM Pricing and Licensing

---

24. Quick-Reference: Discovery Questions by Persona

CTO / VP of Engineering

- "How do you maintain operational visibility across your multi-cloud estate today?"
- "What is your biggest operational challenge as you scale your cloud footprint?"
- "How do you balance deployment velocity with operational risk?"
- "What is your strategy for AI-driven operations?"
- "How do you ensure operational consistency across different cloud platforms?"

Chief Risk Officer / Chief Compliance Officer

- "How do you demonstrate continuous operational governance to regulators—not just at audit time?"
- "Can you produce a complete audit trail for any operational action within minutes?"
- "How are you addressing DORA/NIS2 requirements for ICT risk management and incident reporting?"
- "Do you have visibility into the AI systems used in your operations, and how they make decisions?"
- "What is your regulatory fine exposure for operational governance gaps?"

CFO / FinOps Lead

- "What is your current cloud spend, and what proportion do you believe is waste?"
- "How do you govern cloud cost optimisation without risking application performance?"
- "What is the fully loaded cost of a major operational incident in your organisation?"

- "Are your cloud cost optimisation efforts continuous or periodic?"
- "What is the ROI you expect from operational tooling investments?"

Head of SRE / Platform Engineering Lead

- "How many monitoring tools does your team use, and how do you correlate signals across them?"
- "What is your current MTTR for major incidents, and what drives it?"
- "What proportion of your team's time is spent on toil versus proactive improvement?"
- "How do you manage runbook execution across different environments and clouds?"
- "What is your strategy for progressive automation of operational tasks?"

CISO / Head of Security

- "How do you ensure that operational actions across your multi-cloud estate are authenticated, authorised, and auditable?"
- "What is the blast radius if your operational control plane is compromised?"
- "How do you govern AI systems used in your operations from a security perspective?"
- "Do your operational tools support zone-scoped access control with just-in-time privilege elevation?"
- "How do you ensure that operational telemetry does not leak sensitive data across zone boundaries?"

WIIFM: These questions are designed to open conversations, not close them. Use them to demonstrate that you understand the customer's world, not just your own products. The best sellers listen more than they talk in the first meeting. Ask three or four of these questions, listen carefully to the answers, and use what you hear to select the right play and the right entry point. The customer tells you how to sell to them if you ask the right questions and listen.

---

25. Summary: The Sovereign Cloud Operations Thesis

The sovereign cloud operations thesis, in one paragraph, for when you need to articulate it in 30 seconds:

"Every enterprise running workloads across multiple clouds faces three gaps: they cannot see across all their clouds in one view, they cannot govern operational actions consistently across cloud boundaries, and they cannot apply AI-driven intelligence to the full operational picture. IBM closes all three gaps with an integrated platform—Instana for observability, Concert for AI-driven intelligence, Orchestrate for governed action, Turbonomic for resource optimisation—that runs anywhere, respects sovereign boundaries, and produces the audit trail that regulators now demand. We do not replace your clouds; we make them manageable as one estate."

The opportunity is structural, not cyclical. Multi-cloud complexity will increase. Regulatory requirements will tighten. AI will become essential to operations at scale. The organisations that invest now will have a compounding advantage over those that wait. IBM has the portfolio, the architecture, and the deployment flexibility to lead this market. Your job is to connect the customer's pain to the IBM solution—and this guide gives you the tools to do it.

This guide is derived from Sovereign Cloud Operations *by Alan Hamilton (2026), a 312,000-word reference work covering the full technical, architectural, and organisational depth of the discipline. For deeper technical engagement with customer architects, the full book is available via IBM internal distribution.*
